

FEATURES

Maximum temperature coefficient (TCV_{OUT}): 2 ppm/°C

Output noise (0.1 Hz to 10 Hz)

Less than 1 μV p-p at V_{OUT} of 2.048 V typical

Initial output voltage error: ±0.02% (maximum)

Input voltage range: 3 V to 15 V

Operating temperature: -40°C to +125°C

Output current: +10 mA source/-10 mA sink

Low quiescent current: 950 μA (maximum)

Low dropout voltage: 300 mV at 2 mA (V_{OUT} ≥ 3 V)

8-lead SOIC package

APPLICATIONS

Precision data acquisition systems

High resolution data converters

High precision measurement devices

Industrial instrumentation

Medical devices

Automotive battery monitoring

GENERAL DESCRIPTION

The [ADR4520/ADR4525/ADR4530/ADR4533/ADR4540/ADR4550](#) devices are high precision, low power, low noise voltage references featuring ±0.02% maximum initial error, excellent temperature stability, and low output noise.

This family of voltage references uses an innovative core topology to achieve high accuracy while offering industry-leading temperature stability and noise performance. The low, thermally induced output voltage hysteresis and low long-term output voltage drift of the devices also improve system accuracy over time and temperature variations.

A maximum operating current of 950 μA and a maximum low dropout voltage of 300 mV allow the devices to function very well in portable equipment.

The [ADR4520/ADR4525/ADR4530/ADR4533/ADR4540/ADR4550](#) series of references is provided in an 8-lead SOIC package and is available in a wide range of output voltages, all of which are specified over the extended industrial temperature range of -40°C to +125°C.

PIN CONFIGURATION

ADR4520/ADR4525/
ADR4530/ADR4533/
ADR4540/ADR4550

NOTES

1. NC = NO CONNECT.
2. TP = TEST PIN. DO NOT CONNECT.

ABSOLUTE MAXIMUM RATINGS

$T_A = 25^\circ\text{C}$, unless otherwise noted.

Table 9.

Parameter	Rating
Supply Voltage	16 V
Operating Temperature Range	-40°C to $+125^\circ\text{C}$
Storage Temperature Range	-65°C to $+150^\circ\text{C}$
Junction Temperature Range	-65°C to $+150^\circ\text{C}$

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

THERMAL RESISTANCE

θ_{JA} is specified for the worst-case conditions; that is, a device soldered in a circuit board for surface-mount packages.

Table 10. Thermal Resistance

Package Type	θ_{JA}	θ_{JC}	Unit
8-Lead SOIC	120	42	$^\circ\text{C}/\text{W}$

ESD CAUTION

ESD (electrostatic discharge) sensitive device.

Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

NOTES
 1. NC = NO CONNECT.
 2. TP = TEST PIN. DO NOT CONNECT.

10203-002

Figure 2. Pin Configuration

Table 11. Pin Function Descriptions

Pin No.	Mnemonic	Description
1	NC	No Connect. This pin is not connected internally.
2	V _{IN}	Input Voltage Connection.
3	NC	No Connect. This pin is not connected internally.
4	GND	Ground.
5	NC	No Connect. This pin is not connected internally.
6	V _{OUT}	Output Voltage.
7	NC	No Connect. This pin is not connected internally.
8	TP	Test Pin. Do not connect.

TYPICAL PERFORMANCE CHARACTERISTICS

T_A = 25°C, unless otherwise noted.

TERMINOLOGY

Dropout Voltage (V_{DO})

Dropout voltage, sometimes referred to as supply voltage headroom or supply output voltage differential, is defined as the minimum voltage differential between the input and output such that the output voltage is maintained to within 0.1% accuracy.

$$V_{DO} = (V_{IN} - V_{OUT})_{min}|_{L = constant}$$

Because the dropout voltage depends on the current passing through the device, it is always specified for a given load current. In series mode devices, the dropout voltage typically increases proportionally to the load current (see Figure 6, Figure 21, Figure 37, Figure 52, Figure 67, and Figure 82).

Temperature Coefficient (TCV_{OUT})

The temperature coefficient relates the change in the output voltage to the change in the ambient temperature of the device, as normalized by the output voltage at 25°C. This parameter is determined by the box method, which is represented by the following equation:

$$TCV_{OUT} = \left| \frac{\max\{V_{OUT}(T_1, T_2, T_3)\} - \min\{V_{OUT}(T_1, T_2, T_3)\}}{V_{OUT}(T_2) \times (T_3 - T_1)} \right| \times 10^6$$

where:

TCV_{OUT} is expressed in ppm/°C.

$V_{OUT}(T_x)$ is the output voltage at Temperature T_x .

$T_1 = -40^\circ\text{C}$.

$T_2 = +25^\circ\text{C}$.

$T_3 = +125^\circ\text{C}$.

This three-point method ensures that TCV_{OUT} accurately portrays the maximum difference between any of the three temperatures at which the output voltage of the part is measured.

The TCV_{OUT} for the [ADR4520/ADR4525/ADR4530/ADR4533/ADR4540/ADR4550](#) is fully tested over three temperatures: -40°C , $+25^\circ\text{C}$, and $+125^\circ\text{C}$.

Thermally Induced Output Voltage Hysteresis (ΔV_{OUT_HYS})

Thermally induced output voltage hysteresis represents the change in the output voltage after the device is exposed to a specified temperature cycle. This is expressed as either a shift in voltage or a difference in ppm from the nominal output.

$$\Delta V_{OUT_HYS} = \frac{V_{OUT_25^\circ\text{C}} - V_{OUT_TC}}{V_{OUT_25^\circ\text{C}}} \times 10^6 \text{ [ppm]}$$

where:

$V_{OUT_25^\circ\text{C}}$ is the output voltage at 25°C.

V_{OUT_TC} is the output voltage after temperature cycling.

Long-Term Stability (ΔV_{OUT_LTD})

Long-term stability refers to the shift in the output voltage at 60°C after 1000 hours of operation in a 60°C environment. The ambient temperature is kept at 60°C to ensure that the temperature chamber does not switch randomly between heating and cooling, which can cause instability over the 1000 hour measurement. This is also expressed as either a shift in voltage or a difference in ppm from the nominal output.

$$\Delta V_{OUT_LTD} = \left| \frac{V_{OUT}(t_1) - V_{OUT}(t_0)}{V_{OUT}(t_0)} \right| \times 10^6 \text{ [ppm]}$$

where:

$V_{OUT}(t_0)$ is the V_{OUT} at 60°C at Time 0.

$V_{OUT}(t_1)$ is the V_{OUT} at 60°C after 1000 hours of operation at 60°C.

Line Regulation

Line regulation refers to the change in output voltage in response to a given change in input voltage and is expressed in percent per volt, ppm per volt, or μV per volt change in input voltage. This parameter accounts for the effects of self-heating.

Load Regulation

Load regulation refers to the change in output voltage in response to a given change in load current and is expressed in μV per mA, ppm per mA, or ohms of dc output resistance. This parameter accounts for the effects of self-heating.

Solder Heat Resistance (SHR) Shift

SHR shift refers to the permanent shift in output voltage that is induced by exposure to reflow soldering and is expressed in units of ppm. This shift is caused by changes in the stress exhibited on the die by the package materials when these materials are exposed to high temperatures. This effect is more pronounced in lead-free soldering processes due to higher reflow temperatures.

THEORY OF OPERATION

The [ADR4520/ADR4525/ADR4530/ADR4533/ADR4540/ADR4550](#) series of references uses a unique core topology for extremely high accuracy, stability, and noise performance.

Three parameters contribute to the accuracy of the dc output of a voltage reference: initial accuracy, temperature coefficient, and long-term drift. With an outstanding guaranteed initial error of 0.02% and a low temperature coefficient of 2 ppm/°C maximum, this series of voltage references is perfect for high precision applications. The industry-leading long-term stability of the devices means that systems need less frequent field calibration and that there is a reduction in the costly preshipment system burn-in time.

LONG-TERM DRIFT

One of the key parameters of the [ADR4520/ADR4525/ADR4530/ADR4533/ADR4540/ADR4550](#) references is long-term stability—the output drift over time that the device is powered up. Regardless of output voltage, internal testing during development showed a typical drift of approximately 25 ppm after 1000 hours of continuous, nonloaded operation in a 60°C extremely stable temperature controlled environment.

Note that the majority of the long-term drift typically occurs in the first 200 hours to 300 hours of operation. For systems that require highly stable output voltages over long periods of time, the designer should consider burning in the devices prior to use to minimize the amount of output drift exhibited by the reference over time. See the [AN-713 Application Note](#), *The*

Effect of Long-Term Drift on Voltage References, at www.analog.com for more information regarding the effects of long-term drift and how it can be minimized.

POWER DISSIPATION

The [ADR4520/ADR4525/ADR4530/ADR4533/ADR4540/ADR4550](#) voltage references are capable of sourcing and sinking up to 10 mA of load current at room temperature across the rated input voltage range. However, when used in applications subject to high ambient temperatures, the input voltage and load current should be carefully monitored to ensure that the device does not exceed its maximum power dissipation rating. The maximum power dissipation of the device can be calculated via the following equation:

$$P_D = \frac{T_J - T_A}{\theta_{JA}}$$

where:

P_D is the device power dissipation.

T_J is the device junction temperature.

T_A is the ambient temperature.

θ_{JA} is the package (junction-to-air) thermal resistance.

Due to this relationship, acceptable load current in high temperature conditions may be less than the maximum current sourcing capability of the device. In no case should the part be operated outside of its maximum power rating because doing so may result in premature failure or permanent damage to the device.

APPLICATIONS INFORMATION

BASIC VOLTAGE REFERENCE CONNECTION

The circuit shown in Figure 94 illustrates the basic configuration for the [ADR4520/ADR4525/ADR4530/ADR4533/ADR4540/ADR4550](#) family of voltage references.

Figure 94. [ADR4520/ADR4525/ADR4530/ADR4533/ADR4540/ADR4550](#) Simplified Schematic

INPUT AND OUTPUT CAPACITORS

Input Capacitors

A 1 μF to 10 μF electrolytic or ceramic capacitor can be connected to the input to improve transient response in applications where the supply voltage may fluctuate. An additional 0.1 μF ceramic capacitor should be connected in parallel to reduce supply noise.

Output Capacitors

An output capacitor is required for stability and to filter out low level voltage noise. The minimum value of the output capacitor is shown in Table 12.

Table 12. Minimum C_{OUT} Value

Part Number	Minimum C_{OUT} Value
ADR4520, ADR4525	1.0 μF
ADR4530, ADR4533, ADR4540, ADR4550	0.1 μF

An additional 1 μF to 10 μF electrolytic or ceramic capacitor can be added in parallel to improve transient performance in response to sudden changes in load current; however, the designer should keep in mind that doing so will increase the turn-on time of the device.

LOCATION OF REFERENCE IN SYSTEM

The [ADR4520/ADR4525/ADR4530/ADR4533/ADR4540/ADR4550](#) reference should be placed as close to the load as possible to minimize the length of the output traces and, therefore, the error introduced by the voltage drop. Current flowing through a PCB trace produces an IR voltage drop; with longer traces, this drop can reach several millivolts or more, introducing considerable error into the output voltage of the reference. A 1 inch long, 5 mm wide trace of 1 ounce copper has a resistance of approximately 100 m Ω at room temperature; at a load current of 10 mA, this can introduce a full millivolt of error.

SAMPLE APPLICATIONS

Bipolar Output Reference

Figure 95 shows a bipolar reference configuration. By connecting the output of the [ADR4550](#) to the inverting terminal of an operational amplifier, it is possible to obtain both positive and negative reference voltages. R1 and R2 must be matched as closely as possible to ensure minimal difference between the negative and positive outputs. Resistors with low temperature coefficients must also be used if the circuit is used in environments with large temperature swings; otherwise, a voltage difference develops between the two outputs as the ambient temperature changes.

Figure 95. [ADR4550](#) Bipolar Output Reference

Boosted Output Current Reference

Figure 96 shows a configuration for obtaining higher current drive capability from the [ADR4520/ADR4525/ADR4530/ADR4533/ADR4540/ADR4550](#) references without sacrificing accuracy. The op amp regulates the current flow through the MOSFET until V_{OUT} equals the output voltage of the reference; current is then drawn directly from V_{IN} instead of from the reference itself, allowing increased current drive capability.

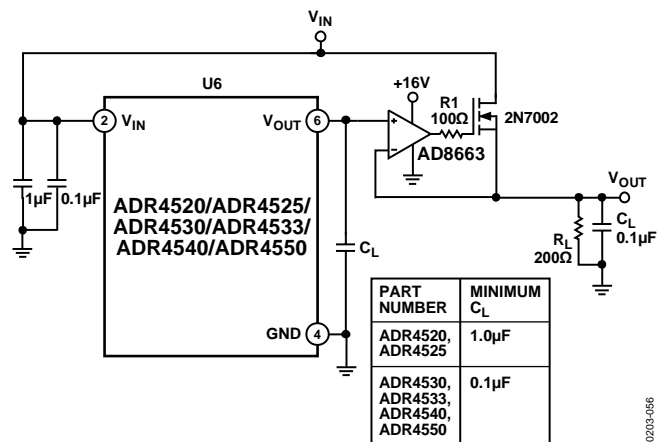

Figure 96. Boosted Output Current Reference

Because the current-sourcing capability of this circuit depends only on the I_{D} rating of the MOSFET, the output drive capability can be adjusted to the application simply by choosing an appropriate MOSFET. In all cases, the V_{OUT} pin should be tied directly to the load device to maintain maximum output voltage accuracy.
