MAX9288/MAX9290

3.12Gbps GMSL Deserializers for Coax or STP Input and MIPI CSI-2 Output

General Description

The MAX9288/MAX9290 gigabit multimedia serial link (GMSL) deserializers receive data from a GMSL serializer over 50Ω coax or 100Ω shielded twisted-pair (STP) cable and output deserialized data on the CSI-2 outputs.

The MAX9290 has HDCP content protection but otherwise is the same as the MAX9288. The deserializers pair with any GMSL serializer capable of coax output. When programmed for STP input, they are backward compatible with any GMSL serializer.

The audio channel supports L-PCM I²S stereo and up to eight channels of L-PCM in TDM mode. Sample rates of 32kHz to 192kHz are supported with sample depth up to 32 bits.

The embedded control channel operates at 9.6kbps to 1Mbps in UART-to-UART and UART-to-I²C modes, and up to 1Mbps in I²C-to-I²C mode. Using the control channel, a μ C can program serializer, deserializer, and peripheral device registers at any time, independent of video timing, and manage HDCP operation (MAX9290). Two GPIO ports are included, allowing display power-up and switching of the backlight, among other uses. A continuously sampled GPI input supports touch-screen controller interrupt requests in display applications.

For use with longer cables, the deserializers have a programmable cable equalizer. The serial input meets ISO 10605 and IEC 61000-4-2 ESD standards. The GMSL supply is 3.0V to 3.6V, the MIPI CSI-2 supply is 1.7V to 1.9V, and the I/O supply is 1.7V to 3.6V.

The devices are available in lead(Pb)-free, 48-pin, 7mm x 7mm TQFN and SWTQFN packages with exposed pad and 0.5mm lead pitch.

Applications

- High-Resolution Automotive Navigation
- Rear-Seat Infotainment
- Megapixel Camera Systems

Simplified Diagram

Benefits and Features

- Ideal for High-Definition Video Applications
 - 4-Lane CSI-2 Output with Up to 1Gbps Per Lane
 - Works with Low-Cost 50Ω Coax Cable and FAKRA Connectors or 100Ω STP
 - 104MHz High-Bandwidth Mode Supports 1920 x 720p/60Hz Display with 24-Bit Color
 - Equalization Allows 15m Cable at Full Speed
 - Up to 192kHz Sample Rate and 32-Bit Sample Depth For 7.1 Channel HD Audio
 - Audio Clock from Audio Source or Audio Sink
 - Color Lookup Table for Gamma Correction
 - CNTL0–CNTL3 Control Outputs for HDMI/MHL
- Multiple Data Rates for System Flexibility
 - Up to 3.12Gbps Serial-Bit Rate
 - 6.25MHz to 104MHz Pixel Clock
 - 9.6kbps to 1Mbps Control Channel in UART, Mixed UART/I²C, or I²C Mode with Clock-Stretch Capability
- Reduces EMI and Shielding Requirements
 - Tracks Spread Spectrum on Input
 - High-Immunity Mode for Maximum Control-Channel Noise Rejection
- Peripheral Features for System Power-Up and Verification
 - Built-In PRBS Tester for BER Testing of the Serial Link
 - Programmable Choice of 8 Default Device Addresses
 - Two Dedicated GPIO Ports
 - Dedicated “Up/Down” GPI for Touch-Screen Interrupt and Other Uses
 - Remote/Local Wake-Up from Sleep Mode
- Meets Rigorous Automotive and Industrial Requirements
 - -40°C to +105°C Operating Temperature
 - ±8kV Contact and ±12kV Air ISO 10605 and IEC 61000-4-2 ESD Protection

Ordering Information appears at end of data sheet.

Absolute Maximum Ratings (Note 1)

AVDD3 to EP	-0.5V to +3.9V
AVDD18, DVDD18 to EP.....	-0.5V to +1.9V
IOVDD to EP	-0.5V to +3.9V
IN+, IN- to EP	-0.5V to +1.9V
LMN_ to EP (15mA current limit).....	-0.5V to +3.9V
CLK_, DOUT_ to EP	-0.5V to +1.9V
All Other Pins to EP	-0.5V to (V _{IOVDD} + 0.5V)
IN+, IN- Short Circuit to Ground or Supply	Continuous

Continuous Power Dissipation (T _A = +70°C)	
TQFN/SWTQFN (derate 40mW/°C above +70°C).....	3200mW
Junction Temperature.....	+150°C
Storage Temperature.....	-65°C to +150°C
Lead Temperature (soldering, 10s)	+300°C
Soldering Temperature (reflow)	+260°C

Note 1: EP connected to PCB ground.

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Package Thermal Characteristics (Note 2)

TQFN/SWTQFN	
Junction-to-Ambient Thermal Resistance (θ _{JA})	25°C/W
Junction-to-Case Thermal Resistance (θ _{JC}).....	1°C

Note 2: Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to www.maximintegrated.com/thermal-tutorial.

DC Electrical Characteristics

(V_{AVDD18} = V_{DVDD18} = 1.7V to 1.9V, V_{AVDD3} = 3.0V to 3.6V, V_{IOVDD} = 1.7V to 3.6V, R_L = 100Ω ±1% (differential), EP connected to PCB ground (GND), T_A = -40°C to +105°C, unless otherwise noted. Typical values are at V_{AVDD18} = V_{DVDD18} = V_{IOVDD} = 1.8V, V_{AVDD3} = 3.3V, T_A = +25°C.) (Note 3)

AC Electrical Characteristics (continued)

($V_{AVDD18} = V_{DVDD18} = 1.7V$ to $1.9V$, $V_{AVDD3} = 3.0V$ to $3.6V$, $V_{IOVDD} = 1.7V$ to $3.6V$, $R_L = 100\Omega \pm 1\%$ (differential), EP connected to PCB ground (GND), $T_A = -40^\circ C$ to $+105^\circ C$, unless otherwise noted. Typical values are at $V_{AVDD18} = V_{DVDD18} = V_{IOVDD} = 1.8V$, $V_{AVDD3} = 3.3V$, $T_A = +25^\circ C$.)

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS
Clock End of Transmission Time	t_{EOT}	Transmitted time interval from the start of $t_{HS-TRAIL}$ or $t_{CLK-TRAIL}$ to start of the LP-11 state following a HS burst			105ns + 12 x UI	ns
HS Exit Time	$t_{HS-EXIT}$	Time that the transmitter drives LP-11 following a HS burst	100			ns
Start of Transmission: Data Prepare Time	$t_{HS-PREPARE}$	Time that the transmitter drives the data lane LP-00 line state immediately before the HS-0 line state starting the HS transmission	40ns + 4 x UI		85ns + 6 x UI	ns
Start of Transition Time	$t_{HS-PREPARE} + t_{HS-ZERO}$	$t_{HS-PREPARE}$ + time that the transmitter drives the HS-0 state prior to transmitting the sync sequence	145ns + 10 x UI			ns
End of Transmission: Data Trail Time	$t_{HS-TRAIL}$	Time that the transmitter drives the flipped differential state after last payload data bit of a HS transmission burst			Max(8 x UI, 60ns + 4 x UI)	ns
LP Transmit Time	t_{LPTX}	Transmitted length of any low-power state period	50			ns

Note 3: Limits are 100% production tested at $T_A = +105^\circ C$. Limits over the operating temperature range are guaranteed by design and characterization, unless otherwise noted.

Note 4: To provide a mid level, leave the input open, or, if driven, put driver in high impedance. High-impedance leakage current must be less than $\pm 10\mu A$.

Note 5: I_{IN_min} due to voltage drop across the internal pullup resistor.

Note 6: Not production tested. Guaranteed by design.

Note 7: HDCP enabled (MAX9290 only). IOVDD current is not production tested. For the MAX9288 (or when HDCP is disabled on the MAX9290), subtract the HDCP supply current, as shown in [Table 25](#).

Note 8: Specified pin to ground.

Note 9: Specified pin to all supply/ground.

Note 10: Not production tested, guaranteed by characterization.

Note 11: Measured in serial link bit times. Bit time = $1/(30 \times f_{PIXEL})$ for BWS = 0 or open. Bit time = $1/(40 \times f_{PIXEL})$ for BWS = 1.

Typical Operating Characteristics

Typical Operating Characteristics (continued)

($V_{AVDD18} = V_{DVDD18} = V_{IOVDD} = 1.8V$, $V_{AVDD3} = 3.3V$, $T_A = +25^\circ C$, unless otherwise noted.)

Pin Configuration

Pin Description

PIN	NAME	FUNCTION
1	INTOUT	A/V Status Register Interrupt Output. Indicates new data in the A/V status registers. INTOUT is reset when the A/V status registers are read.
2	GPI	General-Purpose Input with Internal Pull-down to EP. The serializer GPO (or INT) output follows GPI.
3	I2CSEL	I ² C Select. Control channel interface protocol select input with internal pull-down to EP. Set I2CSEL = high to select I ² C interface. Set I2CSEL = low to select UART interface.
4	GPIO0	Open-Drain, General-Purpose Input/Output, with Internal 60kΩ Pull-up to IOVDD
5	BWS	Three-Level Bus Width Select Input. Set BWS to the same level on both sides of the serial link. Set BWS = low, with 6kΩ (max) pull-down for 24-bit mode. Set BWS = high, with 6kΩ (max) pull-up to IOVDD for 32-bit mode. Set BWS = open for high-bandwidth mode.
6, 47	AVDD3	3.3V Analog Power Supply. Bypass AVDD3 to EP with 0.1μF and 0.001μF capacitors as close as possible to the device with the smaller capacitor closest to AVDD3.
7	IN+	Noninverting Coax/Twisted-Pair Serial Input
8	IN-	Inverting Coax/Twisted-Pair Serial Input

Pin Description (continued)

PIN	NAME	FUNCTION
9	MS	Mode Select with Internal Pulldown to EP. MS sets the control-link mode when CDS = high. Set MS = low, to select base mode. Set MS = high to select the bypass mode. MS sets autostart mode when CDS = low.
10, 23, 37	DVDD18	1.8V Digital Power Supply. Bypass DVDD18 to EP with 0.1 μ F and 0.001 μ F capacitors as close as possible to the device with the smaller value capacitor closest to DVDD18.
11	GPIO1	Open-Drain, General-Purpose Input/Output, with Internal 60k Ω Pullup to IOVDD
12	EQS	Equalizer Select Input, with Internal Pulldown to EP. The state of EQS latches upon power-up or when resuming from power-down mode ($\overline{\text{PWDN}}$ = low). Leave EQS open for 10.7dB equalizer boost (EQTUNE = 1001). Connect EQS to IOVDD with a 30k Ω resistor for 5.2dB equalizer boost (EQTUNE = 0100).
13	RX/SDA	UART Receive/I ² C Serial Data Input/Output, with Internal 30k Ω Pullup to IOVDD. Function is determined by the state of I2CSEL at power-up. RX/SDA has an open-drain driver and requires a pullup resistor. RX: Input of the deserializer's UART. SDA: Data input/output of the deserializer's I ² C Master/Slave.
14	TX/SCL	UART Transmit/I ² C Serial Clock Input/Output, with Internal 30k Ω Pullup to IOVDD. Function is determined by the state of I2CSEL at power-up. TX/SCL has an open-drain driver and requires a pullup resistor. TX: Output of the deserializer's UART. SCL: Clock input/output of the deserializer's I ² C Master/Slave.
15	$\overline{\text{PWDN}}$	Active-Low, Power-Down Input, with Internal Pulldown to EP. Set $\overline{\text{PWDN}}$ low to enter power-down mode to reduce power consumption.
16	WS	I ² S/TDM Word-Select Input/Output. Powers up as an I ² S output (deserializer provided clock). Set AUDIOMODE bit = '1' to change WS to an input with internal pulldown to GND and supply WS externally (system provided clock).
17	SCK	I ² S/TDM Serial-Clock Input/Output. Powers up as an I ² S output (deserializer provided clock). Set AUDIOMODE bit = '1' to change SCK to an input with internal pulldown to GND and supply SCK externally (system provided clock).
18	SD	I ² S/TDM Serial-Data Output. Disable I ² S/TDM encoding to serial data to use SD as an additional control/data output. Encrypted when HDCP is enabled.
19	ADD2/CNTL2	Address Selection Input/Auxiliary Control Signal Output, with Internal Pulldown to EP. Functions as ADD2 input at power-up or when resuming from power-down mode ($\overline{\text{PWDN}}$ = low), and switches to CNTL2 output automatically after power-up. ADD2: Bit value is latched at power-up or when resuming from power-down mode ($\overline{\text{PWDN}}$ = low). See Table 1. Connect ADD2/CNTL2 to IOVDD with a 30k Ω resistor to set high or leave open to set low. CNTL2: Used only in 32-bit and high-bandwidth mode (BWS = high, open). CNTL2 is mapped from the GMSL serializer's CNTL2 or DIN28 input.

Pin Description (continued)

PIN	NAME	FUNCTION
20	HIM/CNTL1	<p>High-Immunity Mode Input/Auxiliary Control Signal Output With Internal Pulldown to EP. Functions as HIM input at power-up or when resuming from power-down mode ($\overline{\text{PWDN}} = \text{low}$), and switches to CNTL2 output automatically after power-up.</p> <p>HIM: Default HIGHIMM bit value is latched at power-up or when resuming from power-down mode ($\overline{\text{PWDN}} = \text{low}$) and is active-high. Connect HIM/CNTL1 to IOVDD with a 30kΩ resistor to set high or leave open to set low. HIGHIMM can be programmed to a different value after power-up. HIGHIMM in the serializer must be set to the same value.</p> <p>CNTL1: Used only in 32-bit and high-bandwidth mode (BWS = high, open). CNTL1 is mapped from the GMSL serializer's CNTL1, DIN27, or RES input.</p>
21, 43	IOVDD	I/O Supply Voltage. 1.8V to 3.3V logic I/O power supply. Bypass IOVDD to EP with 0.1 μF and 0.001 μF capacitors as close as possible to the device with the smallest value capacitor closest to IOVDD.
22	CDS	Control Direction Selection Input, with Internal Pulldown to EP. Control link direct selection input with internal pulldown to EP. Set CDS = low when the control channel master μC is connected at the serializer. Set CDS = high when the control channel master μC is connected at the deserializer.
24	RES	Reserved. Leave unconnected
25, 36	AVDD18	1.8V Analog Power Supply. Bypass AVDD18 to EP with 0.1 μF and 0.001 μF capacitors as close as possible to the device with the smaller capacitor closest to AVDD18.
26–29, 32–35	DOUT_+, DOUT_-	CSI-2 Data Outputs
30, 31	CLK+, CLK-	CSI-2 Clock Output
38	ADD1/CNTL3	<p>Auxiliary Control Signal Output/Address Selection Input, with Internal Pulldown to EP. Functions as ADD1 input at power-up or when resuming from power-down mode ($\overline{\text{PWDN}} = \text{low}$), and switches to CNTL3 output automatically after power-up.</p> <p>ADD1: Bit value is latched at power-up or when resuming from power-down mode ($\overline{\text{PWDN}} = \text{low}$). See Table 1. Connect ADD1/CNTL3 to IOVDD with a 30kΩ resistor to set high or leave open to set low.</p> <p>CNTL3: Used only in high-bandwidth mode (BWS = open).</p>
39	ADD0/CNTL0	<p>Auxiliary Control Signal Output/Address Selection Input, with Internal Pulldown to EP. Functions as ADD0 input at power-up or when resuming from power-down mode ($\overline{\text{PWDN}} = \text{low}$), and switches to CNTL0 output automatically after power-up.</p> <p>ADD0: Bit value is latched at power-up or when resuming from power-down mode ($\overline{\text{PWDN}} = \text{low}$). See Table 1. Connect ADD0/CNTL0 to IOVDD with a 30kΩ resistor to set high or leave open to set low.</p> <p>CNTL0: Used only in high-bandwidth mode (BWS = open).</p>
40	LOCK	Open-Drain Lock Output, with Internal 60k Ω Pullup to IOVDD. LOCK = high indicates that PLLs are locked with correct serial-word-boundary alignment. LOCK = low indicates that PLLs are not locked or an incorrect serial-word-boundary alignment. LOCK is high when $\overline{\text{PWDN}} = \text{low}$.
41	ERR	Error Output. Open-drain data error detection and/or correction indication output with internal 60k Ω pullup to IOVDD. ERR is high when $\overline{\text{PWDN}}$ is low.

Pin Description (continued)

PIN	NAME	FUNCTION
42	DRS	Data-Rate Select Input. DRS is latched upon power-up or when PWDN transitions low-to-high. Set DRS high for pixel clock rates below 16.66MHz (BWS = low), 12.5MHz (BWS = high), or 36.66MHz (BWS = open). Set DRS = low for faster pixel clock rates.
44	LFLT	Active-Low Open-Drain Line-Fault Output. LFLT has a 60kΩ internal pullup to IOVDD. LFLT = low indicates a line fault. LFLT is high when PWDN = low.
45	LMN0	Line Fault Monitor Input 0 (See Figure 1)
46	LMN1	Line Fault Monitor Input 1 (See Figure 1)
48	CX/TP	Three-Level Coax/Twisted Pair Select Input. Use 6kΩ (max) pullup to IOVDD or pulldown resistor for setting CX/TP = high or low. See Table 12 for function.
—	EP	Exposed Pad. EP is internally connected to device ground. MUST connect EP to the PCB ground plane through an array of vias for proper thermal and electrical performance.

*X = 0 for the serializer address, X = 1 for the deserializer address.

**CX/TP determine the serial-cable type CX/TP = open addresses only for coax mode.

Output Bit Map

The input/output bit width depends on settings of the bus width pin (BWS) and the CSI-2 output mode. [Table 4](#) and [Table 3](#) list the bit map for video signals. [Table 4](#) lists the bit map for control signals. Unused control output bits are pulled low.

Serial Link Signaling and Data Format

The serializer uses differential CML signaling to drive twisted-pair cable and single-ended CML to drive coaxial cable with programmable pre/deemphasis and AC-coupling. The deserializer uses AC-coupling and programmable channel equalization.

Input data is scrambled and then 8b/10b coded (9b/10b in high-bandwidth mode). The deserializer recovers the embedded serial clock, then samples, decodes, and descrambles the data. In 24-bit mode, the first 21 bits contain 18 bits of video data and 3 bits of control data (HS/VS/DE). In 32-bit mode, the first 29 bits contain 24 bits of video data, 3 bits of control data (HS/VS/DE) and two bits of control data (CNTL1/CNTL2). In high-bandwidth mode, the first 24 bits contain video data, or

special control-signal packets. In all modes, the last 3 bits contain the embedded audio channel, the embedded forward control channel, and the parity bit of the serial word ([Figure 14](#), [Figure 15](#), [Figure 16](#)).

GMSL-to-CSI-2 Conversion and Output

The GMSL deserializer recovers the clock from the serialized input signals and extracts the video, audio, and control. Video data are packetized to according to MIPI CSI-2 packet formats and sent out through the MIPI DPHY serial lanes.

Video Data Operation

The device converts the video control signal VS to the CSI-2 Frame Start or Frame End short packet ([Figure 17](#)). The converter also assembles the pixel color data into the CSI-2 long packets based on the formats and/or pixel count programmed by the user ([Figure 18](#), [Figure 19](#), [Figure 20](#), [Figure 21](#), [Figure 22](#), [Figure 23](#), [Figure 24](#), [Figure 25](#), [Figure 26](#), [Figure 27](#), [Figure 28](#), [Figure 29](#), [Figure 30](#), and [Figure 31](#)). DE low period needs to be a minimum 200 PCLK cycles to accommodate SOT and EOT during the DE blanking period.

1. Refer to the GMSL serializer data sheet for details.

2. YUV defaults to muxed input mode (Cb, Y0, Cr, Y1). Set INPUTBW = 1 to use normal input mode (CBY0, CrY1).

3. Data type available when BWS = high or open, only.

*VESA/oLDI bits are mapped to MIPI according to OLDI bit (D4 or register 0x60). Set oLDI bit low when using VESA input or high when using an oLDI input. oLDI defines bits [5:0] as MSB and bits [6:7] as LSB.

**12-bit YUV422 sent using CSI-2 user-defined data type (0x30). The output byte sequence is CB[11:4], Y0[11:4], [CB[3:0], Y0[3:0]], CR[11:4], Y1[11:4], [CR[3:0], and Y1[3:0]].

Auto Pixel-Per-Line Feature

For proper operation, the device requires the information of number of pixels in DE high period. Program the pixel count into registers 0x61 and 0x62. Alternatively, the device can automatically count the number of pixels in DE high period.

Setting the AUTOPPL bit high enables this function. In this mode, the device counts the number of pixels in every DE high period and compares the result with the number of

pixels in the previous DE high period. If both numbers are within ±4 pixels of each other, the deserializer accepts this count as valid count and uses the number to packetize the video data. An AUTOPPL error is issued only when the current pixel count does not match the previous pixel count. An invalid count (±5 or more pixels) stops the packet transmission and issues an AUTOPPL error. This allows the device to tolerate some noise while alerting the user of an error.

Clock Operation

The GMSL deserializer recovers the pixel clock (PCLK) from the serial input. This pixel clock is used to time various functions of the device such as the control signals and MCLK. The pixel, along with the CSI data type, determines the CSI HS clock (CLK+/-). When the clocks are stable, the LOCK pin goes high and the clock transmitter starts the SOT, HS prepare and HS zero sequences and transmits the HS clock in HS differential mode. If the device loses of lock, the clock lane is disabled, and the clock transmitter pulls the line to stop state (LP-11).

Data-Rate Selection and CSI-2 Clock Limitations

Three factors affect the overall useable clock range of the GMSL deserializers: The valid clock range of the GMSL serial input, the MIPI CSI-2 output, and the data bit width. [Table 5](#) lists the valid PCLK range at various CSI-2 output modes. [Table 6](#) shows the valid CSI-2 output-channel bit rate.

1. Refer to the GMSL serializer data sheet for details.
2. RAW datatype defaults to single load. Set INPUTBW = 1 to use double input mode (output sequence PA0, PB0, PA1, PB1).
3. Data type available when BWS = high or open, only.

Figure 35. Audio Channel Input Format

GMSL Clock Range

The deserializer uses the DRS pin/bit and the BWS input to set the GMSL pixel clock frequency range (Table 5). Set DRS = 1 for low data rate pixel clock frequency range of 6.25MHz to 16.66MHz. Set DRS = 0 for high data rate pixel clock frequency range of 12.5MHz to 104MHz.

CSI-2 Clock Range

the CSI-2 ports operate from 80Mbps to 1000Mbps per channel. The CSI-2 output bit rate can be calculated from the PCLK rate by the following equation:

$$\text{CSI RATE} = \text{PCLK} \times \text{WIDTH/LANES}$$

where:

PCLK = Input PCLK rate

LANES = Number of CSI-2 lanes used

WIDTH = Bit width of the input data (see Table 5 or Table 6)

High-Bandwidth Mode

The deserializer uses a 27-bit high-bandwidth mode to support 24-bit RGB at 104MHz pixel clock. Set BWS = open in both the serializer and deserializer to use high-bandwidth mode. In high-bandwidth mode, the deserializer decodes HS, VS, DE, and CNTL[3:0] from special packets. Packets are sent by replacing a pixel before the rising edge and after the falling edge of the HS, VS, and DE signals. However, for CNTL[3:0], which is not always continuously sampled, packets always replace a pixel before the transition of the sampled CNTL[3:0]. Keep

HS, VS, and DE low pulse widths at least two pixel clock cycles. By default, CNTL[3:0] are sampled continuously when DE is low. CNTL[3:0] are sampled only on HS/VS transitions when DE is high. If DE triggering of encoded packets is not desired, set the serializer's DISDETRIG = 0 and the CNTLTRIG bits to their desired value (register 0x15) to change the CNTL triggering behavior. Set DETREN = 0 on the deserializer when DE is not periodic.

Audio Channel

The audio channel supports 8kHz to 192kHz audio sampling rates and audio word lengths from 8 bits to 32 bits (2-channel I²S), or 64 to 256 bits (TDM64 to TDM256). The audio bit clock (SCK) does not have to be synchronized with pixel clock. The serializer automatically encodes audio data into a single-bit stream synchronous with pixel clock. The deserializer decodes the audio stream and stores audio words in a FIFO. Audio rate detection uses an internal oscillator to continuously determine the audio data rate and output the audio in I²S format. The audio channel is enabled by default. When the audio channel is disabled, the SD is treated as an auxiliary control signal.

Since the encoded audio data sent through the serial link is synchronized with pixel clock (through ACB), low pixel clock frequencies limit the maximum audio sampling rate. Table 5 lists the maximum audio sampling rate for various pixel clock frequencies. Spread spectrum from the serializer do not affect the I²S/TDM data rate or WS clock frequency.

Audio Channel Input

The audio channel input works with 8-channel TDM and stereo I²S, as well as nonstandard formats. The input format is shown in Figure 35.

The period of the WS can be 8 to 256 SCK periods. The WS frame starts with the falling edge and can be low for 1 to 255 SCK periods. SD is one SCK period, sampled on the rising edge. MSB/LSB order, zero padding, or any other significance assigned to the serial data does not affect operation of the audio channel. The polarity for WS and SCK edges is programmable.

Figure 36, Figure 37, Figure 38, and Figure 39 are examples of acceptable input formats.

Table 4. Control Output Map

CONTROL OUTPUTS	MODE		
	24-BIT MODE (BWS = LOW)	HIGH-BANDWIDTH MODE (BWS = MID)	32-BIT MODE (BWS = HIGH)
CNTL0	Not used	Used*	Not used
CNTL1	Not used	Used*	Used**
CNTL2	Not used	Used*	Used**
CNTL3	Not used	Used*	Not used

Note: See the [High-Bandwidth Mode](#) section for details on timing requirements.

*Outputs used only when the respective color lookup tables are enabled.

**Not encrypted when HDCP is enabled (MAX9290 only).

Table 5. GMSL Data-Rate Selection Table

DRS BIT SETTING	BWS PIN SETTING	PIXEL CLOCK RANGE (MHz)
0 (high data rate)	Low (24-bit mode)	16.66 to 104
	Mid (high-bandwidth mode)	36.66 to 104

Figure 37. 6-Channel TDM (24-Bit Samples, No Padding)

Figure 38. Stereo I²S (24-Bit Samples, Padded with Zeros)

Figure 39. Stereo I²S (16-Bit Samples, No Padding)

Audio Channel Output

WS, SCK, and SD are output with the same timing relationship they had at the audio input, except that WS is always 50% duty cycle (regardless of the duty cycle of WS at the input).

The output format is shown in [Figure 40](#).

WS and SCK can be driven by the audio source (clock master) or the audio sink (clock slave). Buffer underflow and overflow flags are available to the sink as clock slave through I²C for clock frequency adjustment. Data are sampled on the rising edge. WS and SCK polarity is programmable.

Additional MCLK Output for Audio Applications

Some audio DACs, such as the MAX9850, do not require a synchronous main clock (MCLK), while other DACs require a separate MCLK for operation. For audio applications that cannot use WS directly, the deserializer provides a divided MCLK output at either CNTL2 or CNTL0 (determined by MCLKPIN bit setting) at the expense of one less control line. By default, MCLK is turned off. Set MCLKDIV (deserializer register 0x12, D[6:0]) to a nonzero value to enable the MCLK output. Set MCLKDIV to 0x00 to disable MCLK and set CNTL2 or CNTL0 as a control output.

The output MCLK frequency is:

$$f_{\text{MCLK}} = \frac{f_{\text{SRC}}}{\text{MCLKDIV}}$$

where:

f_{SRC} is the MCLK source frequency (see [Table 9](#))

MCLKDIV is the divider ratio from 1 to 127

Choose MCLKDIV values so that f_{MCLK} is not greater than 60MHz. MCLK frequencies derived from pixel clock (MCLKSRC = 0) are not affected by spread-spectrum settings in the deserializer. Enabling spread spectrum

in the serializer, however, introduces spread spectrum into MCLK. Spread-spectrum settings of either device do not affect MCLK frequencies derived from the internal oscillator. The internal oscillator frequency ranges from 100MHz to 150MHz over all process corners and operating conditions. Alternatively, set MCLKWS = 1 (0x15 D1) to output WS from MCLK.

Audio Output Timing Sources

The deserializer has multiple options for audio data output timing. By default, the deserializer provides the output timing based on the incoming data rate (through a FIFO) and an internal oscillator.

To use a system-sourced clock, set the AUDIOMODE bit to 1 (D5 of register 0x02) to set WS and SCK as inputs on the deserializer side. The deserializer uses a FIFO to smooth out the differences in input and output audio timing. Registers 0x78 and 0x79 store the FIFO overflow/underflow information for use with external WS/SCK timing. The FIFO drops data packets during FIFO overflow. By default, the FIFO repeats the last audio packet during FIFO underflow when no audio data is available. Set the AUDUFBEH bit (D2 of register 0x01D) to 1 to output all zeroes during underflow.

Reverse Control Channel

The serializer uses the reverse control channel to receive I²C/UART, MS, and GPO signals from the deserializer in the opposite direction of the video stream. The reverse control channel and forward video data coexist on the same serial cable forming a bidirectional link. The reverse control channel operates independently from the forward control channel. The reverse control channel is available 2ms after power-up. The serializer temporarily disables the reverse control channel for 500 μ s after starting/stopping the forward serial link.

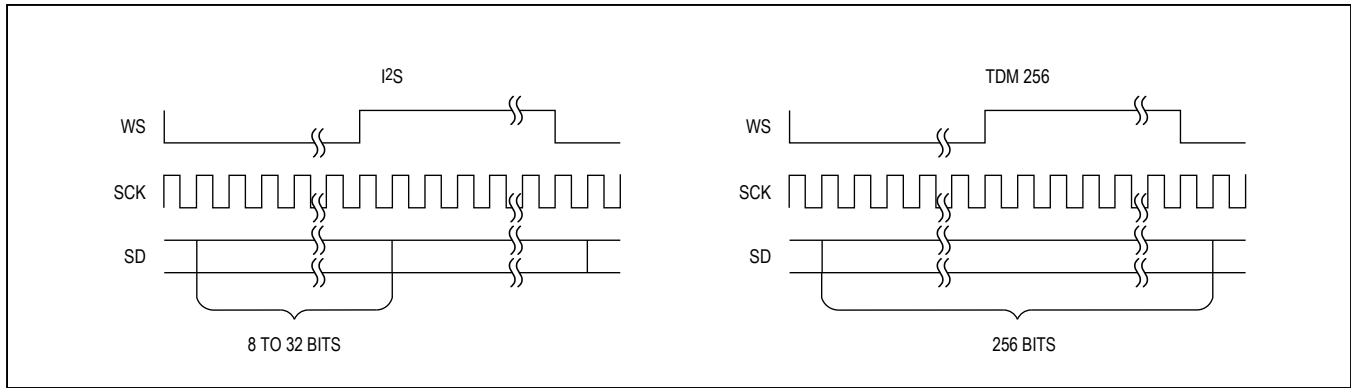

Figure 40. Audio Channel Output Format

Table 9. f_{SRC} Settings

MCLKWS SETTING (REGISTER 0x15, D1)	MCLKSRC SETTING (REGISTER 0x12, D7)	DATA RATE SETTING	BIT-WIDTH SETTING	MCLK SOURCE FREQUENCY (f_{SRC})
0	0	High speed (DRS = 0)	24-bit or high-bandwidth mode	$3 \times f_{PIXEL}$
			32-bit mode	$4 \times f_{PIXEL}$
	Low speed (DRS = 1)	24-bit or high-bandwidth mode	$6 \times f_{PIXEL}$	
		32-bit mode	$8 \times f_{PIXEL}$	
	1	—	—	Internal oscillator (120MHz typ)
1	—	—	—	WS*

*MCLK is not divided when using WS as the MCLK source. MCLK divider must still be set to a nonzero number for MCLK to be enabled.

Control Channel and Register Programming

The control channel is available for the μC to send and receive control data over the serial link simultaneously with the high-speed data. The μC controls the link from either the serializer or the deserializer side to support video-display or image-sensing applications. The control channel between the μC and serializer or deserializer runs in base mode or bypass mode according to the mode-selection input (MS) of the device connected to the μC . Base mode is a half-duplex control channel and bypass mode is a full-duplex control channel. The total maximum forward or reverse control-channel delay is $2\mu s$ (UART) or 2-bit times (I²C) from the input of one device to the output of the other. I²C delay is measured from a START condition to a STOP condition.

UART Interface

In base mode, the μC is the host and can access the registers of both the serializer and deserializer from either side of the link using the GMSL UART protocol. The μC can also program the peripherals on the remote side by

sending the UART packets to the serializer or deserializer, with the UART packets converted to I²C by the device on the remote side of the link. The μC communicates with a UART peripheral in base mode (through INTTYPE register settings), using the half-duplex default GMSL UART protocol of the serializer/deserializer. The device addresses of the serializer and deserializer in base mode are programmable.

When the peripheral interface is I²C, the serializer/deserializer convert UART packets to I²C that have device addresses different from those of the serializer or deserializer. The converted I²C bit rate is the same as the original UART bit rate.

The deserializer uses differential line coding to send signals over the reverse channel to the serializer. The bit rate of the control channel is 9.6kbps to 1Mbps in both directions. The serializer and deserializer automatically detect the control-channel bit rate in base mode. Packet bit-rate changes can be made in steps of up to 3.5 times higher or lower than the previous bit rate. See the [Changing the Clock Frequency](#) section for more information.

Figure 41 shows the UART protocol for writing and reading in base mode between the μ C and the serializer/deserializer.

Figure 42 shows the UART data format. Even parity is used. Figure 43 and Figure 44 detail the formats of the SYNC byte (0x79) and the ACK byte (0xC3). The μ C and the connected slave chip generate the SYNC byte and ACK byte, respectively. Events such as device wake-up and GPI generate transitions on the control channel that can be ignored by the μ C. Data written to the deserializer registers do not take effect until after the ACK byte is sent. This allows the μ C to verify that write commands are received without error, even if the result of the write

command directly affects the serial link. The slave uses the SYNC byte to synchronize with the host UART's data rate. If the GPI or MS inputs of the deserializer toggle while there is control-channel communication, or if a line fault occurs, the control-channel communication is corrupted. In the event of a missed or delayed acknowledge (~1ms due to control channel timeout), the μ C should assume there was an error in the packet transmission or response. In base mode, the μ C must keep the UART Tx/Rx lines high no more than four bit times between bytes in a packet. Keep the UART Tx/Rx lines high for at least 16 bit times before starting to send a new packet.

Figure 41. GMSL UART Protocol for Base Mode

Figure 42. GMSL UART Data Format for Base Mode

Figure 43. SYNC Byte (0x79)

Figure 44. ACK Byte (0xC3)

As shown in Figure 45, the remote-side device converts packets going to or coming from the peripherals from UART format to I²C format and vice versa. The remote device removes the byte number count and adds or receives the ACK between the data bytes of I²C. The I²C bit rate is the same as the UART bit rate.

Interfacing Command-Byte-Only I²C Devices with UART

The deserializers' UART-to-I²C conversion can interface with devices that do not require register addresses, such as the MAX7324 GPIO expander. In this mode, the I²C master ignores the register address byte and directly reads/writes the subsequent data bytes (Figure 46). Change the communication method of the I²C master using the I2CMETHOD bit. I2CMETHOD = 1 sets command-byte-only mode, while I2CMETHOD = 0 sets normal mode where the first byte in the data stream is the register address.

UART Bypass Mode

In bypass mode, the deserializers ignore UART commands from the μC and the μC communicates with the peripherals directly using its own defined UART protocol. The μC cannot access the serializer/deserializer's registers in this

mode. Peripherals accessed through the forward control channel using the UART interface need to handle at least one pixel clock period ±10ns of jitter due to the asynchronous sampling of the UART signal by pixel clock. Set MS = high in the serializer to put the control channel into bypass mode. For applications with the μC connected to the deserializer, set the MS pin on the deserializer. There is a 1ms wait time between switching MS and the bypass control channel being active; do not send a UART command during this time. There is no delay time when switching to bypass mode when the μC is connected to the serializer. Although MS on either the serializer or deserializer sets the control-channel byass mode, only the local-side device (connected to the μC) should be used set bypass mode. Do not switch MS while a UART command is being sent. Do not send a logic-low value longer than 100μs to ensure proper GPO functionality. Bypass mode accepts bit rates down to 10kbps in either direction. See the *GPO/GPI Control* section for GPI functionality limitations. The control-channel data pattern should not be held low longer than 100μs if GPI control is used.

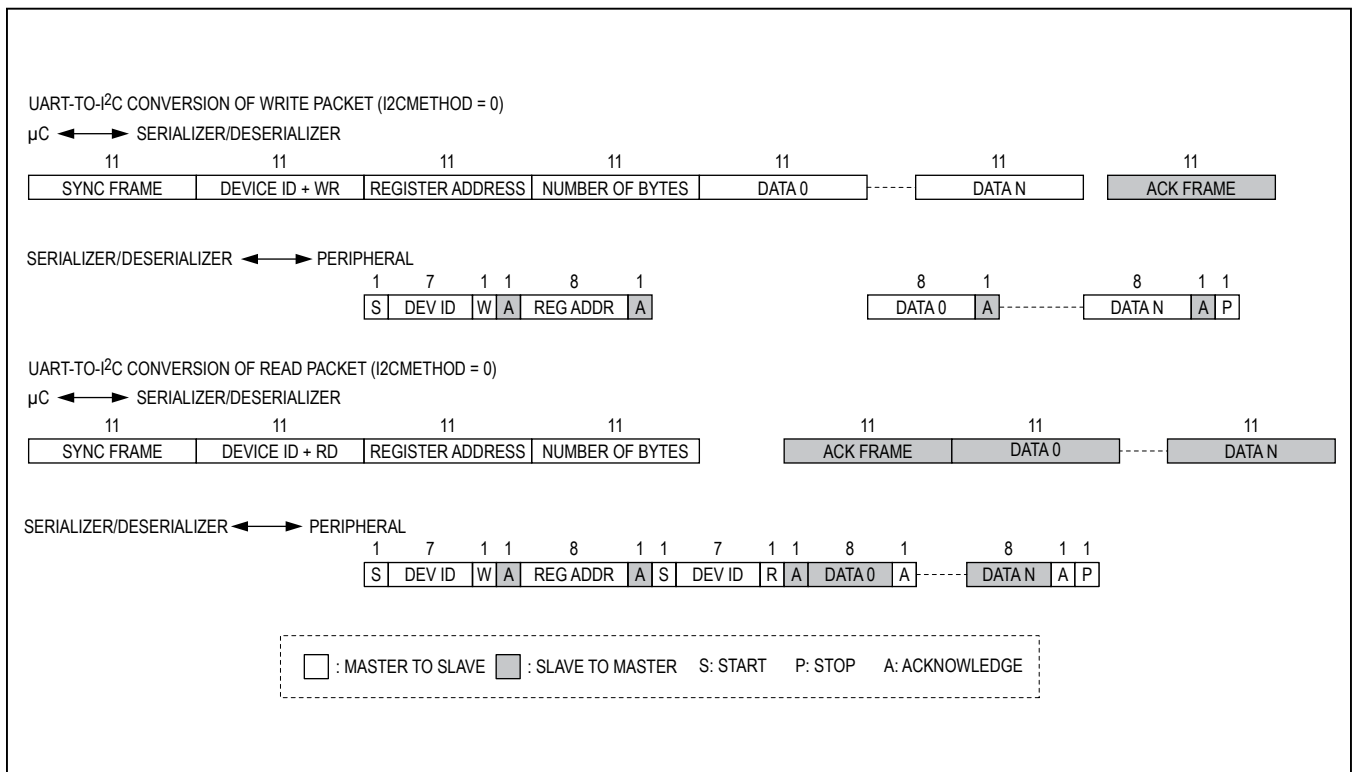

Figure 45. Format Conversion Between GMSL UART and I²C with Register Address (I2CMETHOD = 0)

I²C Interface

In I²C-to-I²C mode, the deserializer’s control-channel interface sends and receives data through an I²C-compatible 2-wire interface. The interface uses a serial-data line (SDA) and a serial-clock line (SCL) to achieve bidirectional communication between master and slave(s). A μC master initiates all data transfers to and from the device and generates the SCL clock that synchronizes the data transfer. When an I²C transaction starts on the local-side device’s control-channel port, the remote-side

device’s control-channel port becomes an I²C master that interfaces with remote-side I²C peripherals. The I²C master must accept clock stretching that is imposed by the deserializer (holding SCL low). The SDA and SCL lines operate as both an input and an open-drain output. Pullup resistors are required on SDA and SCL. Each transmission consists of a START condition (Figure 6) sent by a master, followed by the device’s 7-bit slave address plus a R/W bit, a register address byte, one or more data bytes, and finally a STOP condition.

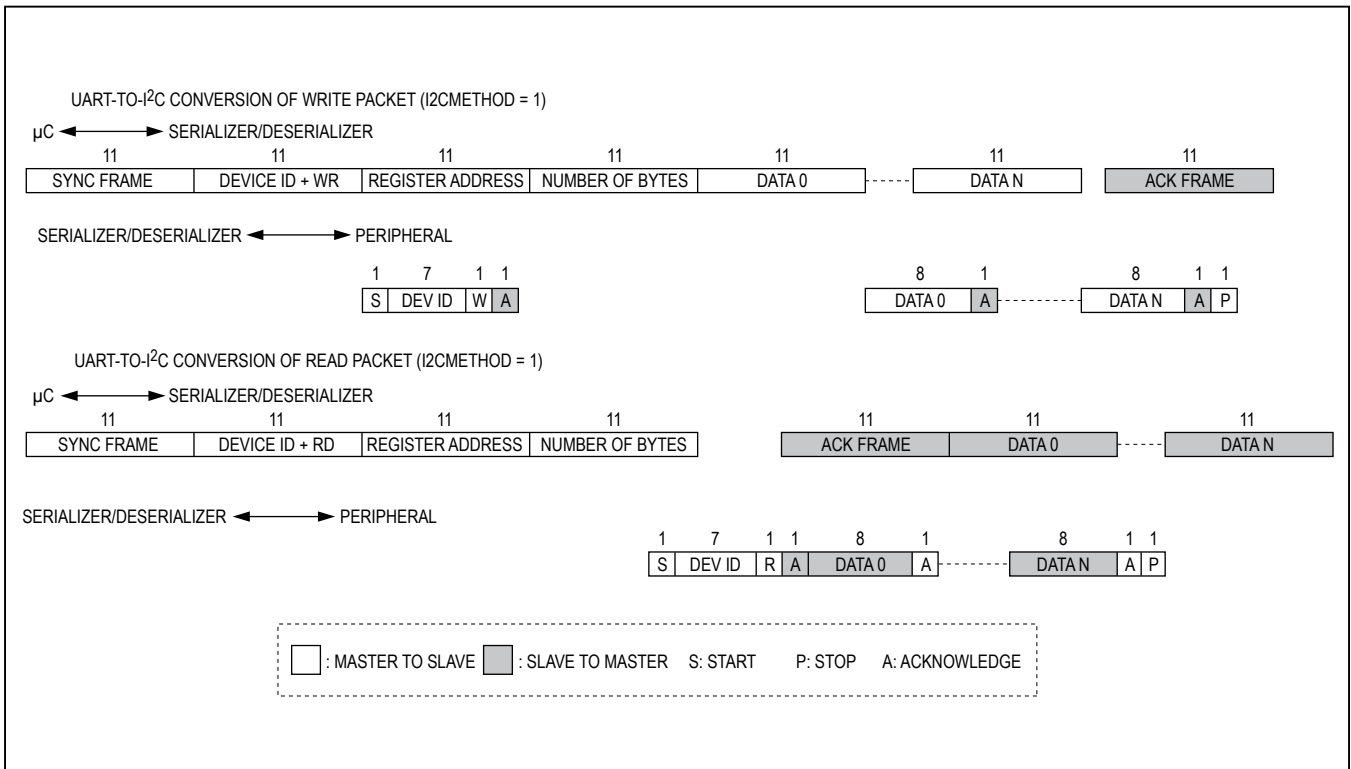

Figure 46. Format Conversion Between GMSL UART and I²C without Register Address (I²CMETHOD = 1)

START and STOP Conditions

Both SCL and SDA remain high when the interface is not busy. A master signals the beginning of a transmission with a START (S) condition by transitioning SDA from high to low while SCL is high (see Figure 47). When the master has finished communicating with the slave, it issues a STOP (P) condition by transitioning SDA from low to high while SCL is high. The bus is then free for another transmission.

Bit Transfer

One data bit is transferred during each clock pulse (Figure 48). The data on SDA must remain stable while SCL is high.

Acknowledge

The acknowledge bit is a clocked 9th bit that the recipient uses to handshake receipt of each byte of data (Figure 49). Thus, each byte transferred effectively requires 9 bits. The master generates the 9th clock pulse, and the recipient pulls down SDA during the acknowledge clock pulse. The SDA line is stable low during the high period of the clock pulse. When the master is transmitting to the slave device, the slave device generates the acknowledge bit because the slave device is the recipient. When the slave device is transmitting to the master, the master generates the acknowledge bit because the master is the recipient. The device generates an acknowledge even when the forward control channel is not active. To prevent acknowledge generation when the forward control channel is not active, set the I2CLOCKACK bit low.

Figure 47. START and STOP Conditions

Figure 48. Bit Transfer

Slave Address

The deserializers have 7-bit long slave addresses. The bit following a 7-bit slave address is the R/W bit, which is

low for a write command and high for a read command. The slave address for the deserializer is XX01XXX1 for read commands and XX01XXX0 for write commands. See [Figure 50](#).

Figure 49. Acknowledge

Figure 50. Slave Address

Bus Reset

The device resets the bus with the I2C START condition for reads. When the R/W bit is set to 1, the deserializers transmit data to the master, thus the master is reading from the device.

Format for Writing

Writes to the deserializers comprise the transmission of the slave address with the R/W bit set to zero, followed by at least 1 byte of information. The first byte of information is the register address or command byte. The register

address determines which register of the device is to be written by the next byte, if received. If a STOP (P) condition is detected after the register address is received, the device takes no further action beyond storing the register address (Figure 51). Any bytes received after the register address are data bytes. The first data byte goes into the register selected by the register address, and subsequent data bytes go into subsequent registers (Figure 52). If multiple data bytes are transmitted before a STOP condition, these bytes are stored in subsequent registers because the register addresses autoincrement.

Figure 51. Format for I2C Write

Figure 52. Format for Write to Multiple Registers

Format for Reading

The deserializers are read using the internally stored register address as an address pointer, the same way the stored register address is used as an address pointer for a write. The pointer autoincrements after each data byte is read using the same rules as for a write. Thus, a read is initiated by first configuring the register address by performing a write (Figure 53). The master can now read consecutive bytes from the device, with the first data byte being read from the register address pointed by the previously written register address. Once the master sends a NACK, the device stops sending valid data.

I²C Communication with Remote-Side Devices

The deserializers support I²C communication with a peripheral on the remote side of the communication link using SCL clock stretching. While multiple masters can reside on either side of the communication link, arbitration is not provided. The connected masters need to support SCL clock stretching. The remote-side I²C bit rate range must be set according to the local-side I²C bit rate. Supported remote-side bit rates can be found in Table 10. Set the I2CMSTBT (register 0x1C) to set the remote I²C bit rate. If using a bit rate different from 400kbps, local- and remote-side I²C setup and hold times should be adjusted by setting the I2CSLVSH register settings on both sides.

Figure 53. Format for I²C Read

Table 10. I²C Bit-Rate Ranges

LOCAL BIT RATE	REMOTE BIT RATE RANGE	I2CMSTBT SETTING
f > 50kbps	Up to 1Mbps	Any
20kbps > f > 50kbps	Up to 400kbps	Up to 110
f < 20kbps	Up to 10kbps	000

I²C Address Translation

The deserializers support I²C address translation for up to two device addresses. Use address translation to assign unique device addresses to peripherals with limited I²C addresses. Source addresses (address to translate from) are stored in registers 0x18 and 0x1A. Destination addresses (address to translate to) are stored in registers 0x19 and 0x1B.

In a multilink situation where there are multiple deserializers and/or peripheral devices connected to these serializers, the deserializers support broadcast commands to control these multiple devices. Select an unused device address to use as a broadcast device address. Program all the remote-side serializer devices to translate the broadcast device address (source address stored in registers 0x0F, 0x11) to the peripherals' address (destination address stored in registers 0x10, 0x12). Any commands sent to the broadcast address (selected unused address) are sent to all deserializers and/or peripheral devices connected to the deserializers whose addresses match the translated broadcast address.

GPO/GPI Control

GPO on the serializer follows GPI transitions on the deserializer. This GPO/GPI function can be used to transmit signals such as a frame sync in a surround-view camera system. The GPI-to-GPO delay is 0.35ms max. Keep time between GPI transitions to a minimum 0.35ms. This includes transitions from the other deserializer in coax splitter mode. Bit D4 of register 0x06 in the deserializer stores the GPI input state. GPO is low after power-up. The μ C can set GPO by writing to the SETGPO register bit. Do not send a logic-low value on the deserializer RX/SDA input (UART mode) longer than 100 μ s in either base or bypass mode to ensure proper GPO/GPI functionality. GPO/GPI commands will override and corrupt an I²C/UART command in progress.

Line Equalizer

The deserializer includes an adjustable line equalizer to further compensate cable attenuation at high frequencies. The cable equalizer has 11 selectable levels of compensation from 2.1dB to 13dB (Table 11). To select other equalization levels, set the corresponding register bits in the deserializer (0x05 D[3:0]). Use equalization in the

deserializer, together with preemphasis in the serializer, to create the most reliable link for a given cable.

HS/VS/DE Tracking

The deserializer has tracking to filter out HS/VS/DE bit or packet errors. HS/VS/DE tracking is on by default when the device is in high-bandwidth mode (BWS = open), and off by default when in 24-bit or 32-bit mode (BWS = low or high). Set/clear HVTREN (D6 of register 0x15) to enable/disable HS/VS tracking. Set/clear DETREN (D5 of register 0x15) to enable/disable DE tracking. By default, the device uses a partial and full periodic tracking of HS/DE. Set HVTRMODE = 0 (D4 of register 0x15) to disable full periodic tracking. HS/VS/DE tracking can be turned on in 24-bit and 32-bit modes to track and correct against bit errors in HS/VS/DE link bits.

Serial Input

The device can receive serial data from two kinds of cable: 100 Ω twisted pair and 50 Ω coax. (Contact the factory for devices compatible with 75 Ω cables).

Table 11. Cable Equalizer Boost Levels

BOOST SETTING (0x05 D[3:0])	TYPICAL BOOST GAIN (dB)
0000	2.1
0001	2.8
0010	3.4
0011	4.2
0100	5.2 Power-up default when EQS is set high
0101	6.2
0110	7
0111	8.2
1000	9.4
1001	10.7 Power-up default when EQS is set low
1010	11.7
1011	13

Coax Splitter Mode

In coax mode, OUT+ and OUT- of the serializer are active. This enables the use as a 1:2 splitter (Figure 54). In coax mode, connect OUT+ to IN+ of the deserializer. Connect OUT- to IN- of the second deserializer. Control-channel data is broadcast from the serializer to both deserializers and their attached peripherals. Assign a unique address to send control data to one deserializer. Leave all unused IN_ pins unconnected, or connect them to ground through

50Ω and a capacitor for increased power-supply rejection. If OUT- is not used, connect OUT- to AVDD through a 50Ω resistor (Figure 55). When there are μCs at the serializer, and at each deserializer, only one μC can communicate at a time. Disable forward and reverse channel links according to the communicating deserializer connection to prevent contention in I²C-to-I²C mode. Use ENREVP or ENREVN register bits to disable/enable the control channel link. In UART mode, the serializer provides arbitration of the control-channel link.

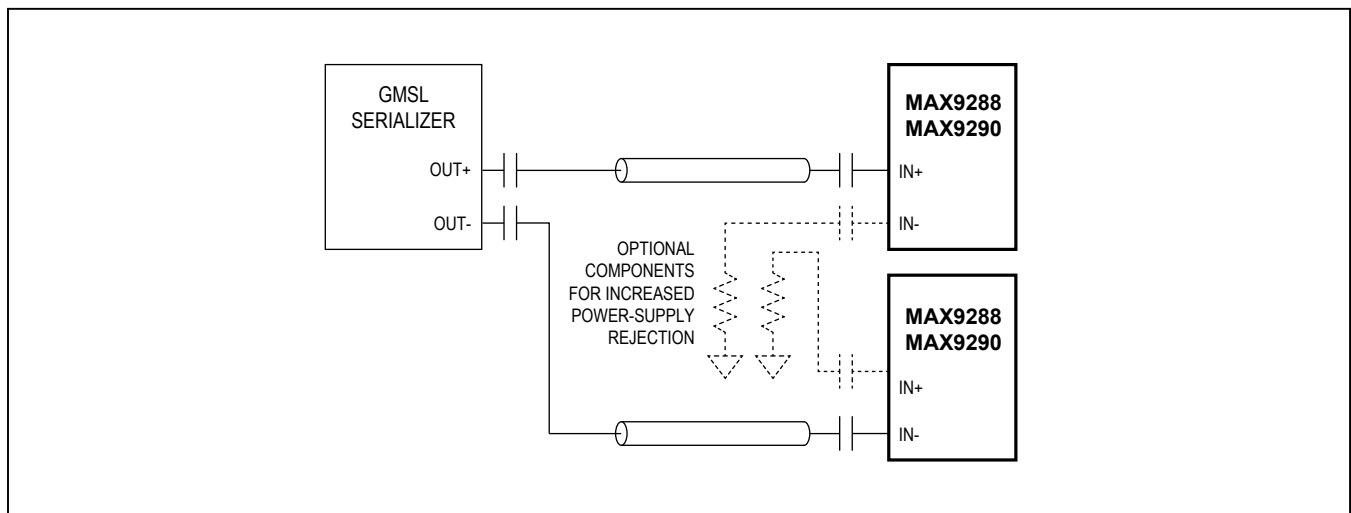

Figure 54. 2:1 Coax Splitter Connection Diagram

Figure 55. Coax Connection Diagram

Table 12. Configuration Input Map

CX/TP	FUNCTION
High	Coax+ input. 7-bit device address is XXXXXX0 (bin).
Mid	Coax- input. 7-bit device address is XXXXXX1 (bin).
Low	Twisted-pair input. 7-bit device address is XXXXXX0 (bin).

Cable Type Configuration Input

CX/TP determine the power-up state of the serial input. In coax mode, CX/TP also determine which coax input is active, along with the default device address (Table 12).

Color Lookup Tables

The deserializer includes three color lookup tables (LUT) to support automatic translation of pixel values. The LUT can be used for RGB666, RGB888, and user-defined generic 8-bit CSI-2 outputs. This feature can be used for color gamma correction, brightness/contrast or for other purposes. There are three lookup tables, each 8 bits wide and 256 entries deep, enabling a 1-to-1 translation of 8-bit input values to any 8-bit output value for each color (24 bits total).

Programming and Verifying LUT Data

The μ C must set the LUTPROG register bit to 1 before programming and verifying the tables. To program a LUT, the μ C generates a write packet with register address set to the assigned register address for respective LUT (0x7D, 0x7E, or 0x7F). The deserializer writes data in the packet to the respective LUT starting from the LUT address location set in the LUTADDR register. Successive bytes in the data packet are written to the next LUT address location; however, each new data-packet write starts from

the address location stored in the LUTADDR register. Use 0x00 for LUTADDR and 0x00 as the number of bytes field in UART packet, when writing a 256-byte data block, because 8-bit-wide number of bytes field cannot normally represent 9-bit wide “256” value. There is no number of bytes field in I²C-to-I²C modes.

To read back the contents of an LUT, the μ C generates a read packet with register address set to the assigned register address for respective LUT (0x7D, 0x7E, or 0x7F). The deserializer outputs read data from the respective LUT starting from the LUT address location set in the LUT_ADDR register. Similar to the write operation, use 0x00 for LUTADDR and 0x00 as the number of bytes field in UART packet, when reading a 256-byte data block.

LUT Color Translation

After power-up or going out of sleep or power-down modes, LUT translation is disabled and LUT contents are unknown. After program and verify operations are finished, in order to enable LUT translations, set the LUTPROG bit to 0 and set the respective LUT enable bits (RED_LUT_EN, GRN_LUT_EN, BLU_LUT_EN) to 1 to enable the desired LUT translation function. Only the selected colors are translated by the LUT (the other colors are not touched). The μ C does not need to fill in all three color lookup tables if all three color translations are not needed.

After a pixel is deserialized, decoded, and decrypted (if necessary), it is segmented into its color components red, green, and blue (RGB) according to Table 13 and Figure 56. If LUT translation is enabled, each 8-bit pretranslation color value is used as address to the respective LUT table to look up the corresponding (translated) 8-bit color value.

Table 13. Pixel Data Format

DOUT [5:0]	DOUT [11:6]	DOUT [17:12]	DOUT18	DOUT19	DOUT20	DOUT [22:21]	DOUT [24:23]	DOUT [26:25]
R[5:0]	G[5:0]	B[5:0]	HS	VS	DE	R[7:6]	G[7:6]	B[7:6]

Figure 56. LUT Dataflow

LUT Bit Width

In 32-bit and high-bandwidth modes, 24 bits are available for color data (8 bits per color) and each LUT is used for 8-bit to 8-bit color translation. In 24-bit mode, the deserializer can receive only up to 18-bit color (6 bits per color). The LUT tables can translate from 6-bit to 6-bit, using the first 64 locations (0x00 to 0x3F). Program the MSB 2 bits of each LUT value to 00. Alternatively, program full 8-bit values to each LUT for 6-bit to 8-bit color translation.

Recommended LUT Program Procedure

- 1) Write LUTPROG = 1 to register 0x7C. Keep BLULUTEN = 0, GRNLUTEN = 0, REDLUTEN = 0 (write 0x08 to register 0x7C).
- 2) Write contents of red LUT with a single write packet. For 24-bit RGB, use 0x7D as register address and 0x00 as number of bytes (UART only) and write 256 bytes. For 18-bit RGB, use 0x7D as register address

and 0x40 as number of bytes (UART only) and write 64 bytes. (Optional: Multiple write packets can be used if LUTADDR is set before each LUT write packet.)

- 3) Read contents of red LUT and verify that they are correct. Use the same register address and number of bytes used in the previous step.
- 4) Repeat steps 2 and 3 for the green LUT, using 0x7E as the register address.
- 5) Repeat steps 2 and 3 for the blue LUT, using 0x7F as the register address.
- 6a) To finish the program and verify routine, without enabling the LUT color translation, write LUTPROG = 0 (write 0x00 to register 0x7C).
- 6b) To finish the program and verify routine, and start LUT color translation, write LUTPROG = 1, BLULUTEN = 1, GRNLUTEN = 1, REDLUTEN = 1 (write 0x07 to register 0x7C).

High-Immunity Reverse Control-Channel Mode

The deserializer contains a high-immunity reverse control-channel mode, which has increased robustness at half the bit rate over the standard GMSL reverse control-channel link (Table 14). Set HIM on the serializer and deserializer to use high-immunity mode at power-up. Set the HIGHIMM bit high in both the serializer and deserializer to enable high-immunity mode at any time after power-up. Set the HIGHIMM bit low in both the serializer and deserializer to use the legacy reverse control-channel mode. The deserializer reverse channel mode is not available for 500µs/1.92ms after the reverse control-channel mode is changed through the serializer/deserializer's HIGHIMM bit setting, respectively. The user must set HIM or the HIGHIMM bits to the same value for proper reverse control-channel communication.

In high-immunity mode, Set HPFTUNE = 00 in the equalizer, if the serial bit rate = [pixel clock x 30 (BWS = low or open) or 40 (BWS = high)] is larger than 1Gbps when BWS is low or high. When BWS = open, set HPFTUNE = 00 when the serial bit rate is larger than 2GBps. In addition, use 47nF AC-coupling capacitors. Note that legacy reverse control-channel mode may not function when using 47nF AC-coupling capacitors.

By default, high-immunity mode uses a 500kbps bit rate. Set REVFAST = 1 (D7 in register 0x1A in the serializer and register 0x11 in the deserializer) in both devices to use a 1Mbps bit rate. Certain limitations apply when using the fast high-immunity mode (Table 15).

Table 14. Reverse Control-Channel Modes

HIGHIMM BIT OR SD/HIM PIN SETTING	REVFAST BIT	REVERSE CONTROL-CHANNEL MODE	MAX UART/I ² C BIT RATE (kbps)
Low (0)	X	Legacy reverse control-channel mode (compatible with all GMSL devices)	1000
High (1)	0	High-immunity mode	500
	1	Fast high-immunity mode	1000

X = Don't care.

Table 15. Fast High-Immunity Mode Requirements

BWS SETTING	ALLOWED PIXEL CLOCK FREQUENCY (MHz)
Low	> 41.66
High	> 30
Open	> 83.33

Fast high-immunity mode requires DRS = 0.

Sleep Mode

The deserializers have sleep mode to reduce power consumption. The devices enter or exit sleep mode by a command from a remote µC using the control channel. Set the SLEEP bit to 1 to initiate sleep mode. Entering sleep mode resets the HDCP registers, but not the configuration registers. The deserializer sleeps after serial link inactivity or 8ms (whichever arrives first) after setting its SLEEP = 1. See the [Link Startup Procedure](#) section for details on waking up the device for different µC and starting conditions.

To wake up from the local side, send an arbitrary control-channel command to the deserializer, wait for 5ms for the chip to power up, and then write 0 to SLEEP register bit to make the wake-up permanent. To wake up from the remote side, enable serialization. The deserializer detects the activity on serial link and then when it locks, it automatically sets its SLEEP register bit to 0.

Power-Down Mode

The deserializers have a power-down mode that further reduces power consumption compared to sleep mode. Set PWDN low to enter power-down mode. In power-down, the parallel outputs remain high impedance. Entering power-down resets the device's registers. Upon exiting power-down, the state of external pins ADD0–ADD2, CX/TP, I2CSEL, DRS, EQS, HIM/CNTL1, and BWS are latched.

Configuration Link

The control channel can operate in a low-speed mode called configuration link in the absence of a clock input. This allows a microprocessor to program configuration registers before starting the video link. An internal oscillator provides the clock for the configuration link. Set CLINKEN = 1 on the serializer to enable configuration link. Configuration link is active until the video link is

enabled. The video link overrides the configuration link and attempts to lock when SEREN = 1.

Link Startup Procedure

Table 16 lists the startup procedure for image-sensing applications. The control channel is available after the video link or the configuration link is established. If the deserializer powers up after the serializer, the control channel becomes unavailable for 2ms after power-up.

Table 16. Startup Procedure for Image-Sensing Applications (CDS = High, Figure 58)

NO.	µC	SERIALIZER		DESERIALIZER
		(AUTOSTART ENABLED)	(AUTOSTART DISABLED)	
—	µC connected to deserializer.	Sets all configuration inputs.	Sets all configuration inputs.	Sets all configuration inputs.
1	Powers up.	Powers up and loads default settings. Establishes video link when valid PCLK available.	Powers up and loads default settings. Goes to sleep after 8ms.	Powers up and loads default settings. Locks to video link signal if available.
2	Writes deserializer configuration bits and gets an acknowledge.			Configuration changed from default settings.
3	Wakes up the serializer by sending dummy packet, and then writing SLEEP = 0 within 8ms. May not get an acknowledge (or gets a dummy acknowledge) if not locked.		Wakes up.	
4	Writes serializer configuration bits. May not get an acknowledge (or gets a dummy acknowledge) if not locked.	Configuration changed from default settings.		
5	If not already enabled, sets SEREN = 1, gets an acknowledge and waits for serial link to be established (~3ms).	Establishes video link when valid PCLK available (if not already enabled).		Locks to video link signal (if not already locked).
6	Begin sending video data to input.	Video data serialized and sent across serial link.		Video data received and deserialized.

High-Bandwidth Digital Content Protection (HDCP)

Note: The explanation of HDCP operation in this data sheet is provided as a guide for general understanding. Implementation of HDCP in a product must meet the requirements given in the HDCP System v1.3 Amendment for GMSL, which is available from DCP.

HDCP has two main phases of operation, authentication and the link integrity check. The μC starts authentication by writing to the START_AUTHENTICATION bit in the GMSL serializer. The GMSL serializer generates a 64-bit random number. The host μC first reads the 64-bit random number from the GMSL serializer and writes it to the deserializer. The μC then reads the GMSL serializer public key selection vector (AKSV) and writes it to the deserializer. The μC then reads the deserializer KSV (BKSV) and writes it to the GMSL serializer. The μC begins checking BKSV against the revocation list. Using the cipher, the GMSL serializer and deserializer calculate a 16-bit response value, R_0 and R_0' , respectively. The GMSL amendment for HDCP reduces the 100ms minimum wait time allowed for the receiver to generate R_0' (specified in HDCP rev 1.3) to 128 pixel clock cycles in the GMSL amendment.

There are two response-value comparison modes, internal comparison and μC comparison. Set EN_INT_COMP = 1 to select internal comparison mode. Set EN_INT_COMP = 0 to select μC comparison mode. In internal comparison mode, the μC reads the deserializer response R_0' and writes it to the GMSL serializer. The GMSL serializer compares R_0' to its internally generated response value R_0 , and sets R0_RI_MATCHED. In μC comparison mode, the μC reads and compares the R_0/R_0' values from the GMSL serializer/deserializer.

During response-value generation and comparison, the host μC checks for a valid BKSV (having 20 1s and 20 0s is also reported in BKSV_INVALID) and checks BKSV against the revocation list. If BKSV is not on the list and the response values match, the host authenticates the link. If the response values do not match, the μC resamples the response values (as described in HDCP rev 1.3, Appendix C). If resampling fails, the μC restarts authentication by setting the RESET_HDCP bit in the GMSL serializer. If BKSV appears on the revocation list, the host cannot transmit data that requires protection. The host knows when the link is authenticated and decides when to output data requiring protection. The μC performs a link integrity check every 128 frames or every $2\text{s} \pm 0.5\text{s}$. The GMSL serializer/deserializer generate response values

every 128 frames. These values are compared internally (internal comparison mode) or can be compared in the host μC .

In addition, the GMSL serializer/deserializer provide response values for the enhanced link verification. Enhanced link verification is an optional method of link verification for faster detection of loss-of-synchronization. For this option, the GMSL serializer and deserializer generate 8-bit enhanced link-verification response values (PJ and PJ') every 16 frames. The host must detect three consecutive PJ/PJ' mismatches before resampling.

Encryption Enable

The GMSL link transfers either encrypted or nonencrypted data. To encrypt data, the host μC sets the encryption enable (ENCRYPTION_ENABLE) bit in both the GMSL serializer and deserializer. The μC must set ENCRYPTION_ENABLE in the same VSYNC cycle in both the GMSL serializer and deserializer (no internal VSYNC falling edges between the two writes). The same timing applies when clearing ENCRYPTION_ENABLE to disable encryption.

Note: ENCRYPTION_ENABLE enables/disables encryption on the GMSL irrespective of the content. To comply with HDCP, the μC must not allow content requiring encryption to cross the GMSL unencrypted.

The μC must complete the authentication process before enabling encryption. In addition, encryption must be disabled before starting a new authentication session.

Synchronization of Encryption

The video vertical sync (VSYNC) synchronizes the start of encryption. Once encryption has started, the GMSL generates a new encryption key for each frame and each line, with the internal falling edge of VSYNC and HSYNC. Rekeying is transparent to data and does not disrupt the encryption of video or audio data.

Repeater Support

The GMSL serializer/deserializer include features to build an HDCP repeater. An HDCP repeater receives and decrypts HDCP content and then encrypts and transmits on one or more downstream links. A repeater can also use decrypted HDCP content (e.g., to display on a screen). To support HDCP repeater-authentication protocol, the deserializer has a REPEATER register bit. This register bit must be set to 1 by a μC (most likely on the repeater module). Both the GMSL serializer and deserializer use SHA-1 hash-value calculation over the assembled KSV lists. HDCP GMSL links support a maximum of 15 receivers (total number including the ones in repeater modules).

If the total number of downstream receivers exceeds 14, the μC must set the MAX_DEVS_EXCEEDED register bit when it assembles the KSV list.

HDCP Authentication Procedures

The GMSL serializer generates a 64-bit random number exceeding the HDCP requirement. The GMSL serializer/deserializer internal one-time programmable (OTP) memories contain a unique HDCP keyset programmed at the factory. The host μC initiates and controls the HDCP authentication procedure. The GMSL serializer and deserializer generate HDCP authentication response values for the verification of authentication. Use the following

procedures to authenticate the HDCP GMSL encryption (refer to the HDCP 1.3 Amendment for GMSL for details). The μC must perform link integrity checks while encryption is enabled (see Table 17). Any event that indicates that the deserializer has lost link synchronization should retrigger authentication. The μC must first write 1 to the RESET_HDCP bit in the GMSL serializer before starting a new authentication attempt.

HDCP Protocol Summary

Table 17, Table 18, and Table 19 list the summaries of the HDCP protocol. These tables serve as an implementation guide only. Meet the requirements in the GMSL amendment for HDCP to be in full compliance.

Table 17. Startup, HDCP Authentication, and Normal Operation (Deserializer is Not a Repeater)—First Part of the HDCP Authentication Protocol

NO.	μC	HDCP GMSL SERIALIZER	HDCP GMSL DESERIALIZER
1	Initial state after power-up.	Powers up waiting for HDCP authentication.	Powers up waiting for HDCP authentication.
2	Makes sure that A/V data not requiring protection (low-value content) is available at the GMSL serializer inputs (such as blue or informative screen). Alternatively, uses the FORCE_VIDEO and FORCE_AUDIO bits of the GMSL serializer to mask A/V data at the input of the GMSL serializer. Starts the link by writing SEREN = H or link starts automatically if AUTOS is low.	—	—
3	—	Starts serialization and transmits low-value content A/V data.	Locks to incoming data stream and outputs low-value content A/V data.
4	Reads the locked bit of the deserializer and makes sure the link is established.	—	—
5	Optionally writes a random-number seed to the GMSL serializer.	Combines seed with internally generated random number. If no seed provided, only internal random number is used.	—
6	If HDCP encryption is required, starts authentication by writing 1 to the START_AUTHENTICATION bit of the GMSL serializer.	Generates (stores) AN, and resets the START_AUTHENTICATION bit to 0.	—
7	Reads AN and AKSV from the GMSL serializer and writes to the deserializer.	—	Generates R0' triggered by the μC 's write of AKSV.
8	Reads the BKSV and REPEATER bit from the deserializer and writes to the GMSL serializer.	Generates R0, triggered by the μC 's write of BKSV.	—

Table 17. Startup, HDCP Authentication, and Normal Operation (Deserializer is Not a Repeater)—First Part of the HDCP Authentication Protocol (continued)

NO.	μC	HDCP GMSL SERIALIZER	HDCP GMSL DESERIALIZER
9	Reads the INVALID_BKSV bit of the GMSL serializer and continues with authentication if it is 0. Authentication can be restarted if it fails (set RESET_HDCP = 1 before restarting authentication).	—	—
10	Reads R0' from the deserializer and reads R0 from the GMSL serializer. If they match, continues with authentication; otherwise, retries up to two more times (optionally, GMSL serializer comparison can be used to detect if R0/R0' match). Authentication can be restarted if it fails (set RESET_HDCP = 1 before restarting authentication).	—	—
11	Waits for the VSYNC falling edge (internal to the GMSL serializer) and then sets the ENCRYPTION_ENABLE bit to 1 in the deserializer and GMSL serializer (if the FC is not able to monitor VSYNC, it can utilize the VSYNC_DET bit in the GMSL serializer).	Encryption enabled after the next VSYNC falling edge.	Decryption enabled after the next VSYNC falling edge.
12	Checks that BKSV is not in the Key Revocation list and continues if it is not. Authentication can be restarted if it fails. Note: Revocation list check can start after BKSV is read in step 8.	—	—
13	Starts transmission of A/V content that needs protection.	Performs HDCP encryption on high-value content A/V data.	Performs HDCP decryption on high-value content A/V data.

Table 18. Link Integrity Check (Normal)—Performed Every 128 Frames After Encryption is Enabled

NO.	μC	HDCP GMSL SERIALIZER	HDCP GMSL DESERIALIZER
1	—	Generates Ri and updates the RI register every 128 VSYNC cycles.	Generates Ri' and updates the RI' register every 128 VSYNC cycles.
2	—	Continues to encrypt and transmit A/V data.	Continues to receive, decrypt, and output A/V data.
3	Every 128 video frames (VSYNC cycles) or every 2s.	—	—
4	Reads RI from the GMSL serializer.	—	—
5	Reads RI' from the deserializer.	—	—
6	Reads RI again from the GMSL serializer and makes sure it is stable (matches the previous RI that it has read from the GMSL serializer). If RI is not stable, go back to step 5.	—	—
7	If RI matches RI', the link integrity check is successful; go back to step 3.	—	—
8	If RI does not match RI', the link integrity check fails. After the detection of failure of link integrity check, the FC makes sure that A/V data not requiring protection (low-value content) is available at the GMSL serializer inputs (such as blue or informative screen). Alternatively, the FORCE_VIDEO and FORCE_AUDIO bits of the GMSL serializer can be used to mask A/V data input of the GMSL serializer.	—	—
9	Writes 0 to the ENCRYPTION_ENABLE bit of the GMSL serializer and deserializer.	Disables encryption and transmits low-value content A/V data.	Disables decryption and outputs low-value content A/V data.
10	Restarts authentication by writing 1 to the RESET_HDCP bit followed by writing 1 to the START_AUTHENTICATION bit in the GMSL serializer.	—	—

Table 19. Optional Enhanced Link Integrity Check—Performed Every 16 Frames After Encryption is Enabled

NO.	μC	HDCP GMSL SERIALIZER	HDCP GMSL DESERIALIZER
1	—	Generates PJ and updates the PJ register every 16 VSYNC cycles.	Generates PJ' and updates the PJ' register every 16 VSYNC cycles.
2	—	Continues to encrypt and transmit A/V data.	Continues to receive, decrypt, and output A/V data.
3	Every 16 video frames, reads PJ from the GMSL serializer and PJ' from the deserializer.	—	—
4	If PJ matches PJ', the enhanced link integrity check is successful; go back to step 3.	—	—
5	If there is a mismatch, retry up to two more times from step 3. Enhanced link integrity check fails after 3 mismatches. After the detection of failure of enhanced link integrity check, the μC makes sure that A/V data not requiring protection (low-value content) is available at the GMSL serializer inputs (such as blue or informative screen). Alternatively, the FORCE_VIDEO and FORCE_AUDIO bits of the GMSL serializer can be used to mask A/V data input of the GMSL serializer.	—	—
6	Writes 0 to the ENCRYPTION_ENABLE bit of the GMSL serializer and deserializer.	Disables encryption and transmits low-value content A/V data.	Disables decryption and outputs low-value content A/V data.
7	Restarts authentication by writing 1 to the RESET_HDCP bit followed by writing 1 to the START_AUTHENTICATION bit in the GMSL serializer.	—	—

Example Repeater Network—Two μ Cs

The example shown in [Figure 58](#) has one repeater and two μ Cs. [Table 20](#) summarizes the authentication operation.

Detection and Action Upon New Device Connection

When a new device is connected to the system, the device must be authenticated and the device's KSV checked against the revocation list. The downstream μ Cs can set the NEW_DEV_CONN bit of the upstream receiver and invoke an interrupt to notify upstream μ Cs.

Figure 57. State Diagram (CDS = High)

Figure 58. Example Network with One Repeater and Two μ Cs (Tx = GMSL Serializer's, Rx = Deserializer's)

Table 20. HDCP Authentication and Normal Operation (One Repeater, Two μCs)—First and Second Parts of the HDCP Authentication Protocol

NO.	μC_B	μC_R	HDCP GMSL SERIALIZER (TX_B1, TX_R1, TX_R2)	HDCP GMSL DESERIALIZER (RX_R1, RX_D1, RX_D2)
			TX_B1 CDS = 0 TX_R1 CDS = 0 TX_R2 CDS = 0	RX_R1 CDS = 1 RX_D1 CDS = 0 RX_D2 CDS = 0
1	Initial state after power-up.	Initial state after power-up.	All: Power-up waiting for HDCP authentication.	All: Power-up waiting for HDCP authentication.
2	—	Writes REPEATER = 1 in RX_R1. Retries until proper acknowledge frame received. Note: This step must be completed before the first part of authentication is started between TX_B1 and RX_R1 by the μC_B (step 7). For example, to satisfy this requirement, RX_R1 can be held at power-down until μC_R is ready to write the REPEATER bit, or μC_B can poll μC_R before starting authentication.	—	—
3	Makes sure that A/V data not requiring protection (low-value content) is available at the TX_B1 inputs (such as blue or informative screen). Alternatively, the FORCE_VIDEO and FORCE_AUDIO bits of TX_B1 can be used to mask A/V data input of TX_B1. Starts the link between TX_B1 and RX_R1 by writing SEREN = H to TX_B1, or link starts automatically if serializer's AUTOS is low.	—	TX_B1: Starts serialization and transmits low-value content A/V data.	RX_R1: Locks to incoming data stream and outputs low-value content A/V data.
4	—	Starts all downstream links by writing SEREN = H to TX_R1, TX_R2, or links start automatically if AUTOS of transmitters are low.	TX_R1, TX_R2: Starts serialization and transmits low-value content A/V data.	RX_D1, RX_D2: Locks to incoming data stream and outputs low-value content A/V data.

Table 20. HDCP Authentication and Normal Operation (One Repeater, Two μ Cs)—First and Second Parts of the HDCP Authentication Protocol (continued)

NO.	μ C_B	μ C_R	HDCP GMSL SERIALIZER (TX_B1, TX_R1, TX_R2)	HDCP GMSL DESERIALIZER (RX_R1, RX_D1, RX_D2)
			TX_B1 CDS = 0 TX_R1 CDS = 0 TX_R2 CDS = 0	RX_R1 CDS = 1 RX_D1 CDS = 0 RX_D2 CDS = 0
5	Reads the locked bit of RX_R1 and makes sure the link between TX_B1 and RX_R1 is established.	Reads the locked bit of RX_D1 and makes sure the link between TX_R1 and RX_D1 is established. Reads the locked bit of RX_D2 and makes sure the link between TX_R2 and RX_D2 is established.	—	—
6	Optionally, writes a random number seed to TX_B1.	Writes 1 to the GPIO_0_FUNCTION and GPIO_1_FUNCTION bits in RX_R1 to change GPIO functionality used for HDCP purpose. Optionally, writes a random-number seed to TX_R1 and TX_R2.	—	—
7	Starts and completes the first part of the authentication protocol between TX_B1, RX_R1 (see steps 6–10 in Table 17).	—	TX_B1: According to commands from μ C_B, generates AN, computes R0.	RX_R1: According to commands from μ C_B, computes R0'.
8	—	When GPIO_1 = 1 is detected, starts and completes the first part of the authentication protocol between the (TX_R1, RX_D1) and (TX_R2, RX_D2) links (see steps 6–10 in Table 17).	TX_R1, TX_R2: According to commands from μ C_R, generates AN, computes R0.	RX_D1, RX_D2: According to commands from μ C_R, computes R0'.
9	Waits for the VSYNC falling edge and then enables encryption on the (TX_B1, RX_R1) link. Full authentication is not complete yet so it makes sure A/V content that needs protection is not transmitted. Since REPEATER = 1 was read from RX_R1, the second part of authentication is required.	—	TX_B1: Encryption enabled after next VSYNC falling edge.	RX_R1: Decryption enabled after next VSYNC falling edge.

Table 20. HDCP Authentication and Normal Operation (One Repeater, Two μ Cs)—First and Second Parts of the HDCP Authentication Protocol (continued)

NO.	μ C_B	μ C_R	HDCP GMSL SERIALIZER (TX_B1, TX_R1, TX_R2)	HDCP GMSL DESERIALIZER (RX_R1, RX_D1, RX_D2)
			TX_B1 CDS = 0 TX_R1 CDS = 0 TX_R2 CDS = 0	RX_R1 CDS = 1 RX_D1 CDS = 0 RX_D2 CDS = 0
10	—	When GPIO_0 = 1 is detected, enables encryption on the (TX_R1, RX_D1) and (TX_R2, RX_D2) links.	TX_R1, TX_R2: Encryption enabled after next VSYNC falling edge.	RX_D1, RX_D2: Decryption enabled after next VSYNC falling edge.
11		Blocks control channel from μ C_B side by setting REVCCEN = FWDCEN = 0 in RX_R1. Retries until proper acknowledge frame received.	—	RX_R1: Control channel from serializer side (TX_B1) is blocked after FWDCEN = REVCCEN = 0 is written.
12	Waits for some time to allow μ C_R to make the KSV list ready in RX_R1. Then polls (reads) the KSV_LIST_READY bit of RX_R1 regularly until proper acknowledge frame is received and bit is read as 1.	Writes BKSVs of RX_D1 and RX_D2 to the KSV list in RX_R1. Then, calculates and writes the BINFO register of RX_R1.	—	RX_R1: Triggered by μ C_R's write of BINFO, calculates hash value (V') on the KSV list, BINFO and the secret-value M0'.
13		Writes 1 to the KSV_LIST_READY bit of RX_R1 and then unblocks the control channel from the μ C_B side by setting REVCCEN = FWDCEN = 1 in RX_R1.	—	RX_R1: Control channel from the serializer side (TX_B1) is unblocked after FWDCEN = REVCCEN = 1 is written.
14	Reads the KSV list and BINFO from RX_R1 and writes them to TX_B1. If any of the MAX_DEVS_EXCEEDED or MAX_CASCADE_EXCEEDED bits is 1, then authentication fails. Note: BINFO must be written after the KSV list.	—	TX_B1: Triggered by μ C_B's write of BINFO, calculates hash value (V) on the KSV list, BINFO and the secret-value M0.	—
15	Reads V from TX_B1 and V' from RX_R1. If they match, continues with authentication; otherwise, retries up to two more times.	—	—	—
16	Searches for each KSV in the KSV list and BKSv of RX_R1 in the Key Revocation list.	—	—	—

Table 20. HDCP Authentication and Normal Operation (One Repeater, Two μCs)—First and Second Parts of the HDCP Authentication Protocol (continued)

NO.	μC_B	μC_R	HDCP GMSL SERIALIZER (TX_B1, TX_R1, TX_R2)	HDCP GMSL DESERIALIZER (RX_R1, RX_D1, RX_D2)
			TX_B1 CDS = 0 TX_R1 CDS = 0 TX_R2 CDS = 0	RX_R1 CDS = 1 RX_D1 CDS = 0 RX_D2 CDS = 0
17	If keys are not revoked, the second part of the authentication protocol is completed.	—	—	—
18	Starts transmission of A/V content that needs protection.	—	All: Perform HDCP encryption on high-value A/V data.	All: Perform HDCP decryption on high-value A/V data.

Notification of Start of Authentication and Enable of Encryption to Downstream Links

HDCP repeaters do not immediately begin authentication upon startup or detection of a new device, but instead wait for an authentication request from the upstream transmitter/repeaters.

Use the following procedure to notify downstream links of the start of a new authentication request:

- 1) Host μC begins authentication with the HDCP repeater’s input receiver.
- 2) When AKSV is written to HDCP repeater’s input receiver, its AUTH_STARTED bit is automatically set and its GPIO1 goes high (if GPIO1_FUNCTION is set to high).
- 3) HDCP repeater’s μC waits for a low-to-high transition on HDCP repeater input receiver’s AUTH_STARTED bit and/or GPIO1 (if configured) and starts authentication downstream.
- 4) HDCP repeater’s μC resets the AUTH_STARTED bit.

Set GPIO0_FUNCTION to high to have GPIO0 follow the ENCRYPTION_ENABLE bit of the receiver. The repeater μC can use this function for notification when encryption is enabled/disabled by an upstream μC.

Applications Information

Self PRBS Test

The serializers include a PRBS pattern generator that works with bit-error verification in the deserializer. To run the PRBS test, first disable HDCP encryption. Next, set DISHSFILT, DISVSFILT, and DISDEFILT to 1, to disable glitch filter in the deserializer. Then, set PRBSEN = 1 (0x04, D5) in the serializer and then in the deserializer. To exit the PRBS test, set PRBSEN = 0 (0x04, D5) in the deserializer and then in the serializer.

Error Checking

The deserializers check the serial link for errors and store the number of decoding errors in the 8-bit registers DECERR (0x0D). If a large number of decoding errors are detected within a short duration (error rate ≥ 1/4), the deserializers lose lock and stop the error counter. The deserializers then attempt to relock to the serial data. DECERR reset upon successful video link lock, successful readout of the register (through μC), or whenever auto error reset is enabled. The deserializers use a separate PRBS register during the internal PRBS test, and DECERR are reset to 0x00.

ERR Output

The deserializers have an open-drain ERR output. This output asserts low whenever the number of decoding errors exceeds the error thresholds during normal operation, or when at least one PRBS error is detected during PRBS test. ERR reasserts high whenever DECERR resets, due to DECERR readout, video link lock, or auto error reset.

Auto Error Reset

The default method to reset errors is to read the respective error registers in the deserializers (0x0D and 0x0E). Auto error reset clears the error counters DECERR and the $\overline{\text{ERR}}$ output $\sim 1\mu\text{s}$ after $\overline{\text{ERR}}$ goes low. Auto error reset is disabled on power-up. Enable auto error reset through AUTORST (0x06, D5). Auto error reset does not run when the device is in PRBS test mode.

Dual μC Control

Usually systems have one microcontroller to run the control channel, located on the serializer side for display applications or on the deserializer side for image-sensing applications. However, a μC can reside on each side simultaneously and trade off running the control channel. In this case, each μC can communicate with the serializer and deserializer and any peripheral devices.

Contention occurs if both μC s attempt to use the control channel at the same time. It is up to the user to prevent this contention by implementing a higher level protocol. In addition, the control channel does not provide arbitration between I²C masters on both sides of the link. An acknowledge frame is not generated when communication fails due to contention. If communication across the serial link is not required, the μC s can disable the forward and reverse control channel using the FWCCEN and REVCCEN bits (0x04, D[1:0]) in the serializer/deserializer. Communication across the serial link is stopped and contention between μC s cannot occur.

As an example of dual μC use in an image-sensing application, the serializer can be in sleep mode and waiting for wake-up by μC on the deserializer side. After wake-up, the serializer-side μC assumes master control of the serializer's registers.

Changing the Clock Frequency

It is recommended that the serial link be enabled after the video clock (f_{pixel}) and the control-channel clock ($f_{\text{UART}}/f_{\text{I}^2\text{C}}$) are stable. When changing the clock frequency, stop the video clock for $5\mu\text{s}$, apply the clock at the new frequency, then restart the serial link or toggle SEREN. On-the-fly changes in clock frequency are possible if the new frequency is immediately stable and without glitches. The reverse control channel remains unavailable for $500\mu\text{s}$ after serial link start or stop. When using the UART interface, limit on-the-fly changes in f_{UART} to factors of less than 3.5 at a time to ensure that the device recognizes the UART sync pattern. For example, when lowering the UART frequency from 1Mbps to 100kbps, first send data at 333kbps then at 100kbps for reduction ratios of 3 and 3.333, respectively.

Spread-Spectrum Clock Tracking

Using a spread-spectrum clock source can reduce EMI/EMC on the serial and MIPI data. The deserializer can track a spread-spectrum signal from the serializer. Use a spread $< \pm 1\%$ for CSI-2 output rates $\leq 400\text{MHz}$. Use a spread $< \pm 0.5\%$ for CSI-2 output rates $> 400\text{MHz}$.

Fast Detection of Loss-of-Synchronization

A measure of link quality is the recovery time from loss-of-synchronization. The host can be quickly notified of loss-of-lock by connecting the deserializer's LOCK output to the GPI input. If other sources use the GPI input, such as a touch-screen controller, the μC can implement a routine to distinguish between interrupts from loss-of-sync and normal interrupts. Reverse control-channel communication does not require an active forward link to operate and accurately tracks the LOCK status of the GMSL link. LOCK asserts for video link only and not for the configuration link.

Providing a Frame Sync (Camera Applications)

The GPI/GPO provide a simple solution for camera applications that require a frame sync signal from the ECU (e.g., surround-view systems). Connect the ECU frame sync signal to the GPI input, and connect GPO output to the camera frame sync input. GPI/GPO has a typical delay of $275\mu\text{s}$. Skew between multiple GPI/GPO channels is typically $115\mu\text{s}$. If a lower skew signal is required, connect the camera's frame sync input to one of the deserializer's GPIOs and use an I²C broadcast write command to change the GPIO output state. This has a maximum skew of $1.5\mu\text{s}$, independent from the used I²C bit rate.

Software Programming of the Device Addresses

The serializers and deserializers have programmable device addresses. This allows multiple GMSL devices, along with I²C peripherals, to coexist on the same control channel. The serializer device address is in register 0x00 of each device, while the deserializer device address is in register 0x01 of each device. To change a device address, first write to the device whose address changes (register 0x00 of the serializer for serializer device address change, or register 0x01 of the deserializer for deserializer device address change). Then write the same address into the corresponding register on the other device (register 0x00 of the deserializer for serializer device address change, or register 0x01 of the serializer for deserializer device address change).

Three-Level Configuration Inputs

CX/TP and BWS are three-level inputs that control the serial interface configuration and power-up defaults. Connect three-level inputs through a pullup resistor to IOVDD to set a high level, a pull-down resistor to GND to set a low level, or open to set a mid level. For digital control, use three-state logic to drive the three-level logic input.

Configuration Blocking

The deserializers can block changes to registers. Set CFGBLOCK to make registers 0x00 to 0x1F as read only. Once set, the registers remain blocked until the supplies are removed or until PWDN is low.

Compatibility with Other GMSL Devices

The deserializers are designed to pair with the MAX9275–MAX9281 serializers, but interoperate with any GMSL serializers. See [Table 21](#) for operating limitations

Key Memory

Each device has a unique HDCP key set that is stored in secure nonvolatile memory (NVM). The HDCP key set consists of 40 56-bit private keys and one 40-bit public key. The NVM is qualified for automotive applications.

HS/VS/DE Inversion

The deserializers use an active-high HS, VS, and DE for encoding and HDCP encryption. Set INVHSYNC, INVVSYNC, and INVDE in the serializer to invert active-low input signals for use with the GMSL devices. Set INVHSYNC, INVVSYNC, and INVDE in the deserializer (register 0x14) to output active-low signals for use with downstream devices.

WS/SCK Inversion

The deserializers use standard polarities for I²S. Set INVWS and INVSCCK in the serializer (register 0x1B) to invert opposite polarity signals for use with the GMSL devices. Set INVWS and INVSCCK in the deserializer (register 0x1D) to output reverse-polarity signals for downstream use.

GPIOs

The deserializers have two open-drain GPIOs available when not used for HDCP purposes (see the [Notification of Start of Authentication and Enable of Encryption to Downstream Links](#) section), GPIO1OUT and GPIO0OUT (0x06, D3 and D1) set the output state of the GPIOs. Setting the GPIO output bits to 0 low pulls the output low, while setting the bits to 1 leaves the output undriven, and pulled high through internal/external pullup resistors. The GPIO input buffers are always enabled. The input states are stored in GPIO1 and GPIO0 (0x06, D2 and D0). Set GPIO1OUT/GPIO0OUT to 1 when using GPIO1/GPIO0 as an input.

Line-Fault Detection

The line-fault detector monitors for line failures such as short to ground, short to battery, and open link for system-fault diagnosis. Figure 1 shows the required external resistor connections. LFLT = low when a line fault is detected and LFLT goes high when the line returns to normal. The line-fault type is stored in 0x08 D[3:0] of the serializer. Filter LFLT with the μ C to reduce the detector's susceptibility to short ground shifts. The fault-detector threshold voltages are referenced to the serializer ground. Additional passive components set the DC level of the cable. If the serializer and GMSL deserializer grounds are different, the link DC voltage during normal operation can vary and cross one of the fault-detection thresholds.

Table 21. MAX9288/MAX9290 Feature Compatibility

FEATURE	GMSL SERIALIZER
HDCP (MAX9290 only)	If feature not supported in serializer, must not be turned on in the MAX9290.
High-bandwidth mode	If feature not supported in serializer, must only use 24-bit and 32-bit modes.
I ² C-to-I ² C	If feature not supported in serializer, must use UART-to-I ² C or UART-to-UART.
Coax	If feature not supported in serializer, must connect unused serial output through 200nF and 50 Ω in series to V _{DD} and set the reverse control channel amplitude to 100mV.
High-immunity control channel	If feature not supported in serializer, must use the legacy reverse control-channel mode.
TDM encoding	If feature not supported in serializer, must use I ² S encoding (with 50% WS duty cycle), if supported.
I ² S encoding	If feature not supported in serializer, must disable I ² S in the MAX9288/MAX9290.

For the fault-detection circuit, select the resistor's power rating to handle a short to the battery. In coax mode, leave the unused line-fault inputs unconnected. To detect the short-together case, refer to Application Note 4709: *GMSL Line-Fault Detection*. [Table 23](#) lists the mapping for line fault types

Internal Input Pulldowns

The control and configuration inputs (except three-level inputs) include a pulldown resistor to GND. External pulldown resistors are not needed.

Choosing I²C/UART Pullup Resistors

I²C and UART open-drain lines require a pullup resistor to provide a logic-high level. There are tradeoffs between power dissipation and speed, and a compromise may be required when choosing pullup resistor values. Every device connected to the bus introduces some capacitance even when the device is not in operation. I²C specifies 300ns rise times (30% to 70%) for fast mode, which is defined for data rates up to 400kbps (see the I²C specifications in the [AC Electrical Characteristics](#) table for details). To meet the fast-mode rise-time requirement, choose the pullup resistors so that rise time $t_R = 0.85 \times R_{PULLUP} \times C_{BUS} < 300\text{ns}$. The waveforms are not recognized if the transition time becomes too slow. The device supports I²C/UART rates up to 1Mbps.

AC-Coupling

AC-coupling isolates the receiver from DC voltages up to the voltage rating of the capacitor. Capacitors at the serializer output and at the deserializer input are needed for proper link operation and to provide protection if either end of the cable is shorted to a battery. AC-coupling blocks low-frequency ground shifts and low-frequency common-mode noise.

Selection of AC-Coupling Capacitors

Voltage droop and the digital sum variation (DSV) of transmitted symbols cause signal transitions to start from different voltage levels. Because the transition time is fixed, starting the signal transition from different voltage levels causes timing jitter. The time constant for an AC-coupled link needs to be chosen to reduce droop and jitter to an acceptable level. The RC network for an AC-coupled link consists of the CML/coax receiver termination resistor (R_{TR}), the CML/coax driver termination resistor (R_{TD}), and the series AC-coupling capacitors (C). The RC time constant for four equal-value series capacitors is $(C \times (R_{TD} + R_{TR}))/4$. R_{TD} and R_{TR} are required to match the transmission line impedance (usually 100Ω

differential, 50Ω single ended). This leaves the capacitor selection to change the system time constant. Use at 0.22μF (using legacy reverse control channel), 47nF (using high-immunity reverse control channel), or larger high-frequency surface-mount ceramic capacitors, with sufficient voltage rating to withstand a short to battery, to pass the lower speed reverse control-channel signal. Use capacitors with a case size less than 3.2mm x 1.6mm to have lower parasitic effects to the high-speed signal.

Power-Supply Circuits and Bypassing

The deserializers use an AVDD18 and DVDD18 of 1.7V to 1.9V and an AVDD3 of 3.0V to 3.6V. All single-ended inputs and outputs except for the serial input derive power from an IOVDD of 1.7V to 3.6V that scale with IOVDD. Proper voltage-supply bypassing is essential for high-frequency circuit stability.

Power-Supply Table

Power-supply currents shown in the [DC Electrical Characteristics](#) table is measured at $V_{IOVDD} = 3.6\text{V}$. If using a different IOVDD voltage, the IOVDD worst-case supply current will vary. HDCP operation (MAX9290 only) draws additional current. This is shown in [Table 24](#).

Cables and Connectors

Interconnect for CML typically has a differential impedance of 100Ω. Use cables and connectors that have matched differential impedance to minimize impedance discontinuities. Coax cables typically have a characteristic impedance of 50Ω, contact the factory for 75Ω operation). [Table 24](#) lists the suggested cables and connectors used in the GMSL link.

Board Layout

Separate LVCMOS logic signals and CML/coax high-speed signals to prevent crosstalk. Use a four-layer PCB with separate layers for power, ground, CML/coax, and LVCMOS logic signals. Layout PCB traces close to each other for a 100Ω differential characteristic impedance for STP. The trace dimensions depend on the type of trace used (microstrip or stripline). Note that two 50Ω PCB traces do not have 100Ω differential impedance when brought close together—the impedance goes down when the traces are brought closer. Use a 50Ω trace for the single-ended output when driving coax.

Route the PCB traces for differential CML channel in parallel to maintain the differential characteristic impedance. Avoid vias. Keep PCB traces that make up a differential pair equal length to avoid skew within the differential pair.

ESD Protection

ESD tolerance is rated for Human Body Model, IEC 61000-4-2, and ISO 10605. The ISO 10605 and IEC 61000-4-2 standards specify ESD tolerance for electronic systems. The serial link inputs are rated for ISO 10605 ESD protection and IEC 61000-4-2 ESD protection. All pins are tested for the Human Body Model. The Human Body Model discharge components are $C_S = 100\text{pF}$ and $R_D = 1.5\text{k}\Omega$ (Figure 59). The IEC 61000-4-2 discharge components are $C_S = 150\text{pF}$ and $R_D = 330\Omega$ (Figure 60). The ISO 10605 discharge components are $C_S = 330\text{pF}$ and $R_D = 2\text{k}\Omega$ (Figure 61).

0xB6	1	GPMEM	Read/write	General-purpose memory byte.	0x00
0xB7 to 0xB9	3	—	Read only	Reserved	0x000000
0xBA to 0xFF	70	KSV_LIST	Read/write	List of KSVs downstream repeaters and receivers (maximum of 14 devices).	All zero

Typical Application Circuit

Ordering Information

PART	PIN-PACKAGE	HDPC
MAX9288GTM+	48 TQFN-EP*	No
MAX9288GTM/V+	48 TQFN-EP*	No
MAX9288GTM/VY+	48 SWTQFN-EP*	No
MAX9290GTM+	48 TQFN-EP*	Yes†
MAX9290GTM/V+	48 TQFN-EP*	Yes†
MAX9290GTM/VY+**	48 SWTQFN-EP*	Yes†

Note: All devices operate over the -40°C to +105°C temperature range.

+Denotes a lead(Pb)-free/RoHS-compliant package.

/V Denotes an automotive-qualified part.

SW = Side-wettable package.

*EP = Exposed pad.

**Future product—contact factory for availability.

†HDPC parts require registration with Digital Content Protection, LLC.

Chip Information

PROCESS: CMOS

Package Information

For the latest package outline information and land patterns (footprints), go to www.maximintegrated.com/packages. Note that a "+", "#", or "-" in the package code indicates RoHS status only. Package drawings may show a different suffix character, but the drawing pertains to the package regardless of RoHS status.

PACKAGE TYPE	PACKAGE CODE	OUTLINE NO.	LAND PATTERN NO.
48 TQFN-EP	T4877+4	21-0144	90-0130
48 SWTQFN-EP	T4877Y+4	21-100045	90-0130

Revision History

REVISION NUMBER	REVISION DATE	DESCRIPTION	PAGES CHANGED
0	3/14	Initial release	—
1	9/14	Added simplified diagram, removed Table 1 and renumbered the subsequent tables, clarified functions, removed future product designations, and corrected typos	1, 28, 33, 48, 49, 51–56, 59, 66, 67, 69–72, 74–77, 79–82, 84, 85, 86, 88–102
2	11/15	Clarified timing requirements	8, 27, 30, 50
3	3/17	Various updates, beginning with <i>AC Electrical Characteristics</i>	12, 18, 21, 26, 58, 61, 62, 67, 71, 80, 84, 86, 90, 99
4	3/18	Deleted QFND package and added side-wettable TQFN (SWTQFN) to <i>General Description, Absolute Maximum Ratings, Package Thermal Characteristics, Pin Configuration, Ordering Information, and Package Information</i>	1, 8, 18, 102

For pricing, delivery, and ordering information, please contact Maxim Direct at 1-888-629-4642, or visit Maxim Integrated's website at www.maximintegrated.com.

Maxim Integrated cannot assume responsibility for use of any circuitry other than circuitry entirely embodied in a Maxim Integrated product. No circuit patent licenses are implied. Maxim Integrated reserves the right to change the circuitry and specifications without notice at any time. The parametric values (min and max limits) shown in the Electrical Characteristics table are guaranteed. Other parametric values quoted in this data sheet are provided for guidance.
